

# A draft assessment for eastern Bering Sea snow crab

Cody Szuwalski

All measures of survey abundance are at or near **all-time lows**.

Survey MMB (morphometrically mature) was -40% compared to last year's all time low.

Small male recruitment signal in  $< 50$  mm carapace width range, but need more years to corroborate given false starts in the past.

# More points for concern

Increased probability of having undergone terminal molt at small sizes in 2021

# More points for concern

Increased probability of having undergone terminal molt at small sizes in 2021

Average clutch fullness scores at all-time lows

# More points for concern

Increased probability of having undergone terminal molt at small sizes in 2021

Average clutch fullness scores at all-time lows

Fishery CPUE at all-time lows in 2021/2022 season

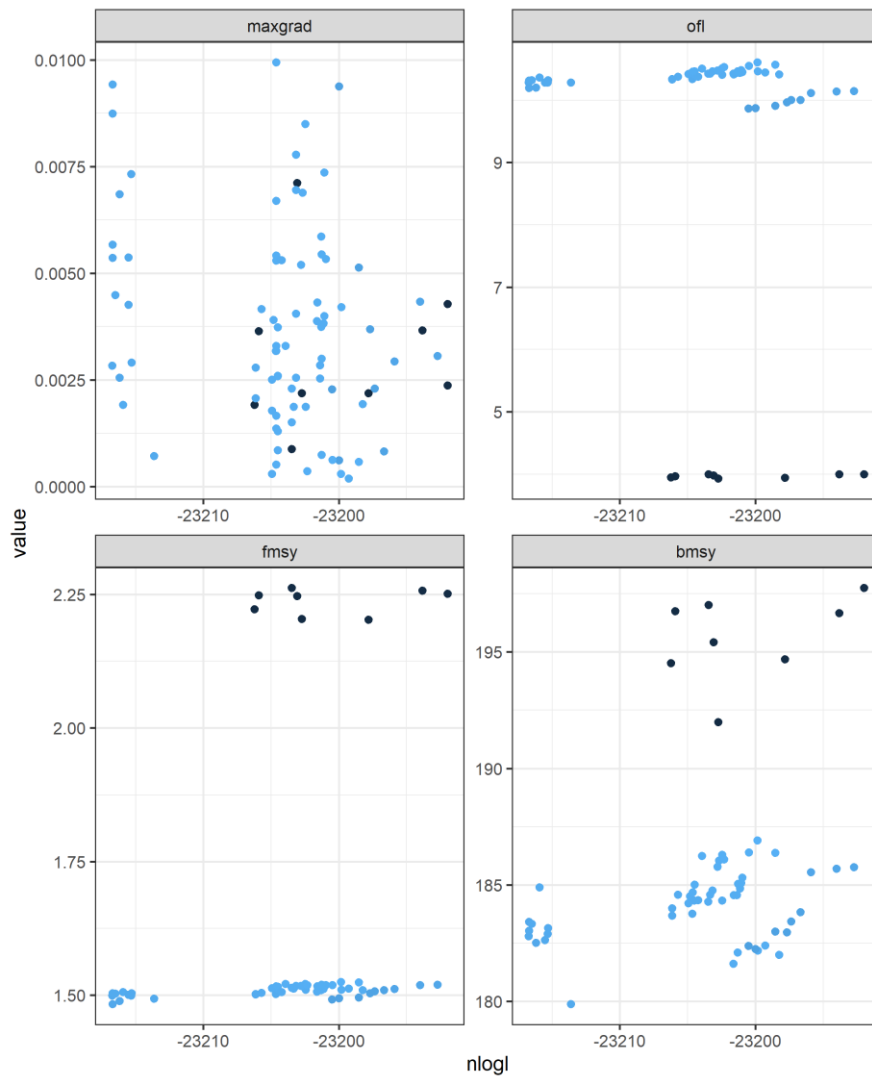

# More points for concern

Increased probability of having undergone terminal molt at small sizes in 2021

Average clutch fullness scores at all-time lows

Fishery CPUE at all-time lows in 2021/2022 season

Bycatch near all-time lows

# Modeling issues

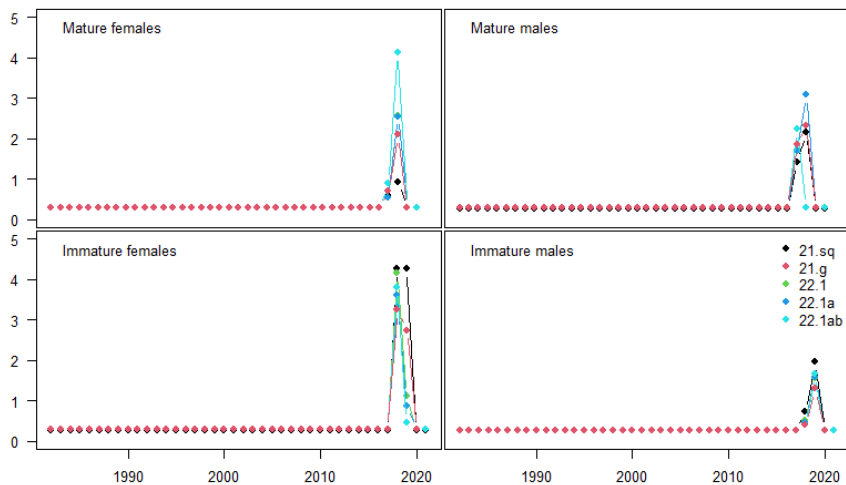

- Move to GMACS was useful, but...
- New data resulted in bimodal management quantities

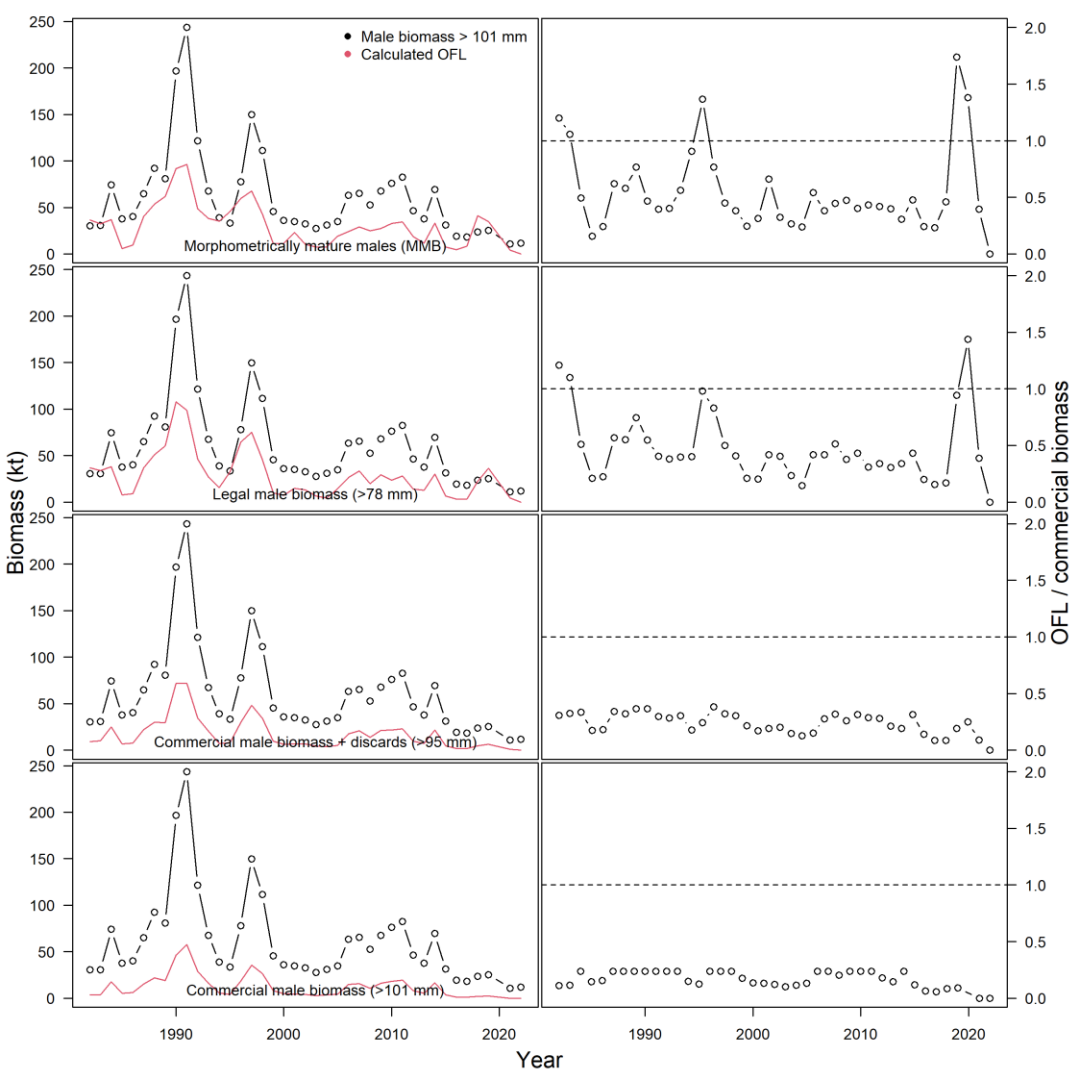

# Modeling issues

- Move to GMACS was useful, but...
- New data resulted in bimodal management quantities
- Bimodality results from two different interpretations about what happened in 2019-2020 and mortality events

# Modeling issues

- Move to GMACS was useful, but...
- New data resulted in bimodal management quantities
- Bimodality results from two different interpretations about what happened in 2019-2020 and mortality events
- Tier 4 rules all close the fishery

# Models presented

- Tier 3
  - 21.1: GMACS model accepted by SSC in June 2022 with prior on M to match status quo model
  - 22.1: 21.1 with updated data
  - 22.1a: 22.1 with initial numbers at size estimated as parameters rather than composition and a scaling factor
  - 22.1ab: 22.1a but from a different mode from the jittering analysis
- Tier 4
  - Morphometrically mature male biomass
  - Legal males (>78 mm carapace width)
  - Males >95 mm carapace width
  - Preferred males (>101 mm carapace width)

# Other things I tried

- Adding penalties on F devs
  - Adding additional year of mortality events (i.e. adding 2020)
  - Non-parametric survey selectivity
  - Reweighting the size composition data
  - Various combinations of the above
  - Began a male only model
- 
- Hoping to incorporate maturity data next year...but unclear if this will overcome issues with not having 2020 data

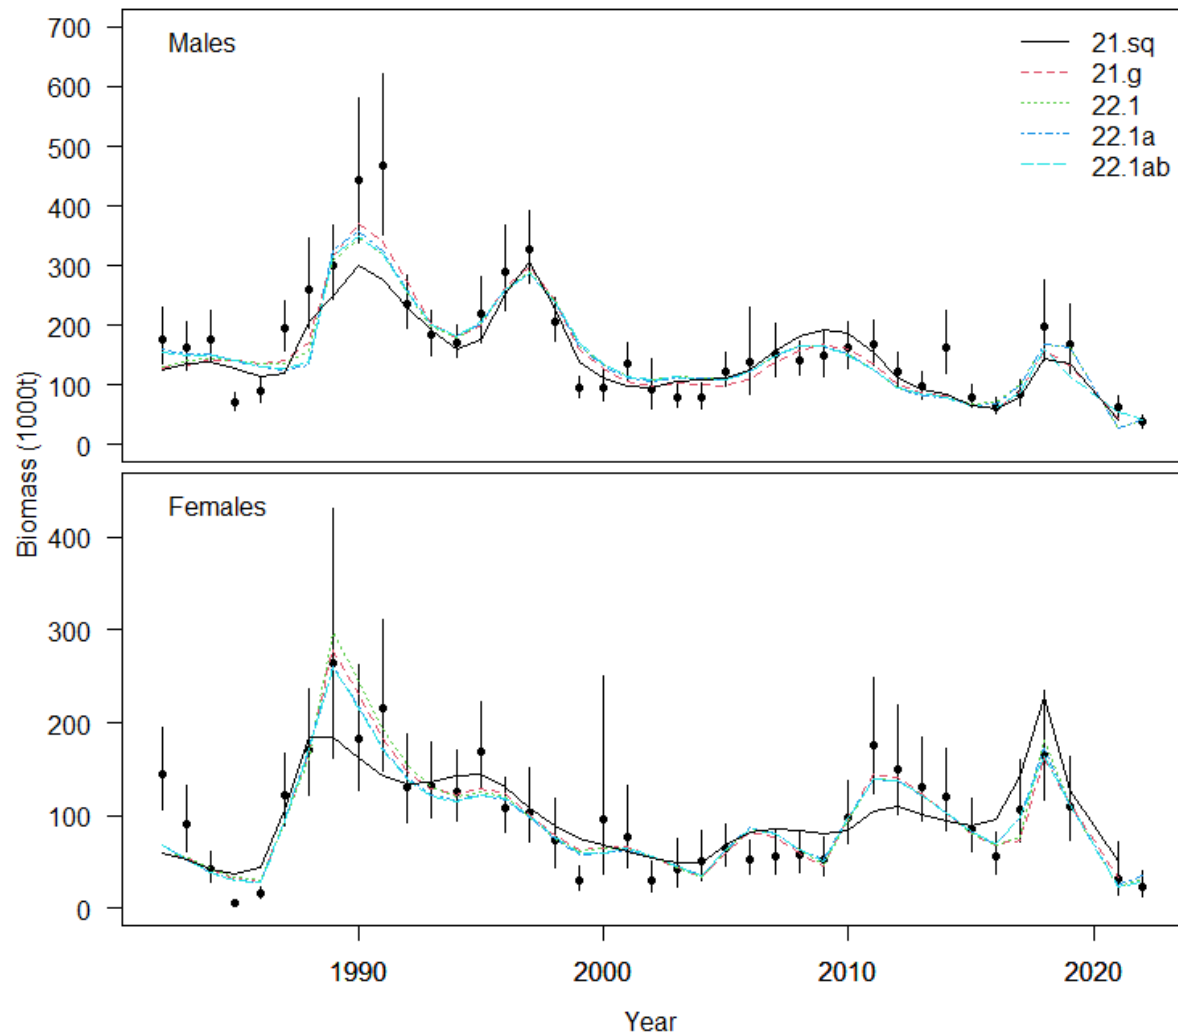

# Decision points

- How to consider a bimodal model?
  - Is it acceptable to use a mode that is a local minimum?
  - 4 criteria: **fits, plausibility, stability, convergence**
- If the bimodal model cannot be justified, is there justification for tier 4 models?
- Martin suggested potentially rolling over the OFL from last year.

Natural mortality		?		?

# Author-preferred model: 22.1ab

- Pros
  - No unrealistic fishing mortality in 2020
  - Decrease in survey  $q$  closer to BSFRF implied  $q$  ('how could MMB go up if the survey went down?')
- Cons
  - Not the best fit (but size composition overweighted)
  - Decrease in survey  $q$  a fairly large departure from the status quo
  - Larger recruitment event in 2015
- Trade-offs
  - Large fishing mortality vs. large recruitment
  - Fits to size composition data
- Overarching issues
  - No 2020 data
  - Probability of having undergone terminal molt
  - Two weeks is not enough time to do an assessment when problems arise

## Two potential histories:

22.1a:

~3 recruitments

Two large mortalities on MMB

Implausibly high F

22.1ab:

One recruitment

One large mortality on MMB

Reasonable Fs

## Two potential histories:

22.1a:

~3 recruitments

Two large mortalities on MMB

Implausibly high F

22.1ab:

One recruitment

One large mortality on MMB

Reasonable Fs

## Estimated fishing mortality

### Two potential histories:

22.1a:

~3 recruitments

Two large mortalities on MMB

Implausibly high F

22.1ab:

One recruitment

One large mortality on MMB

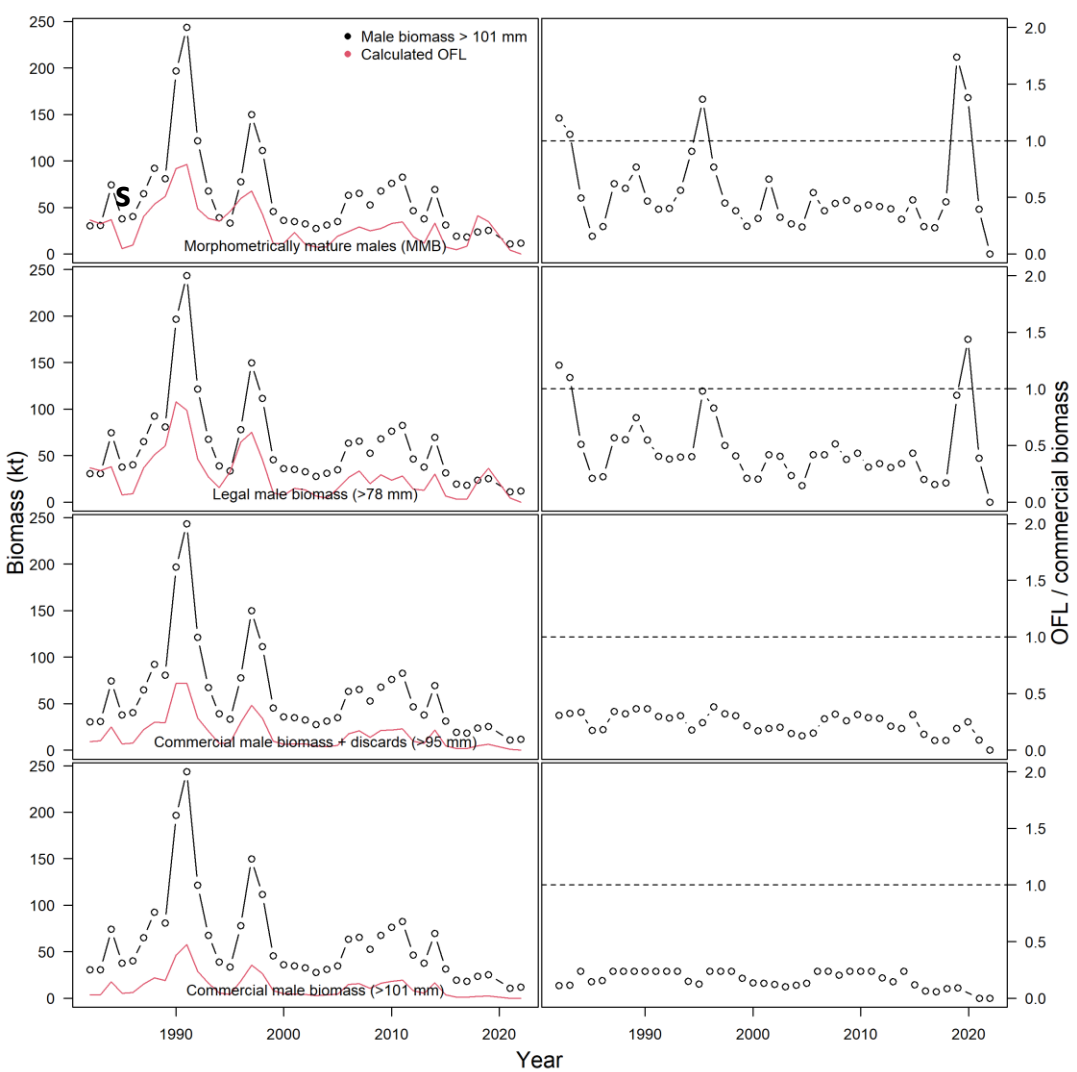

More reasonable Fs

Model	MMB	B35	F35	FOFL	OFL	M	avg_rec	Status
21.sq	26.74	153.42	1.43	0.37	7.50	0.27	106.14	0.17
21.g	23.71	153.33	1.59	0.36	7.89	0.28	131.71	0.15
22.1	39.85	189.12	1.37	0.28	9.06	0.28	161.82	0.21
22.1a	41.21	183.15	1.50	0.32	10.32	0.28	164.02	0.23
22.1ab	96.67	196.38	2.26	0.67	3.98	0.29	180.36	0.49

Among the updated models, 22.1a or 22.1ab are both an improvement over 22.1

Given the difference in plausibility of fishing mortality,  
22.1ab is my author-preferred model

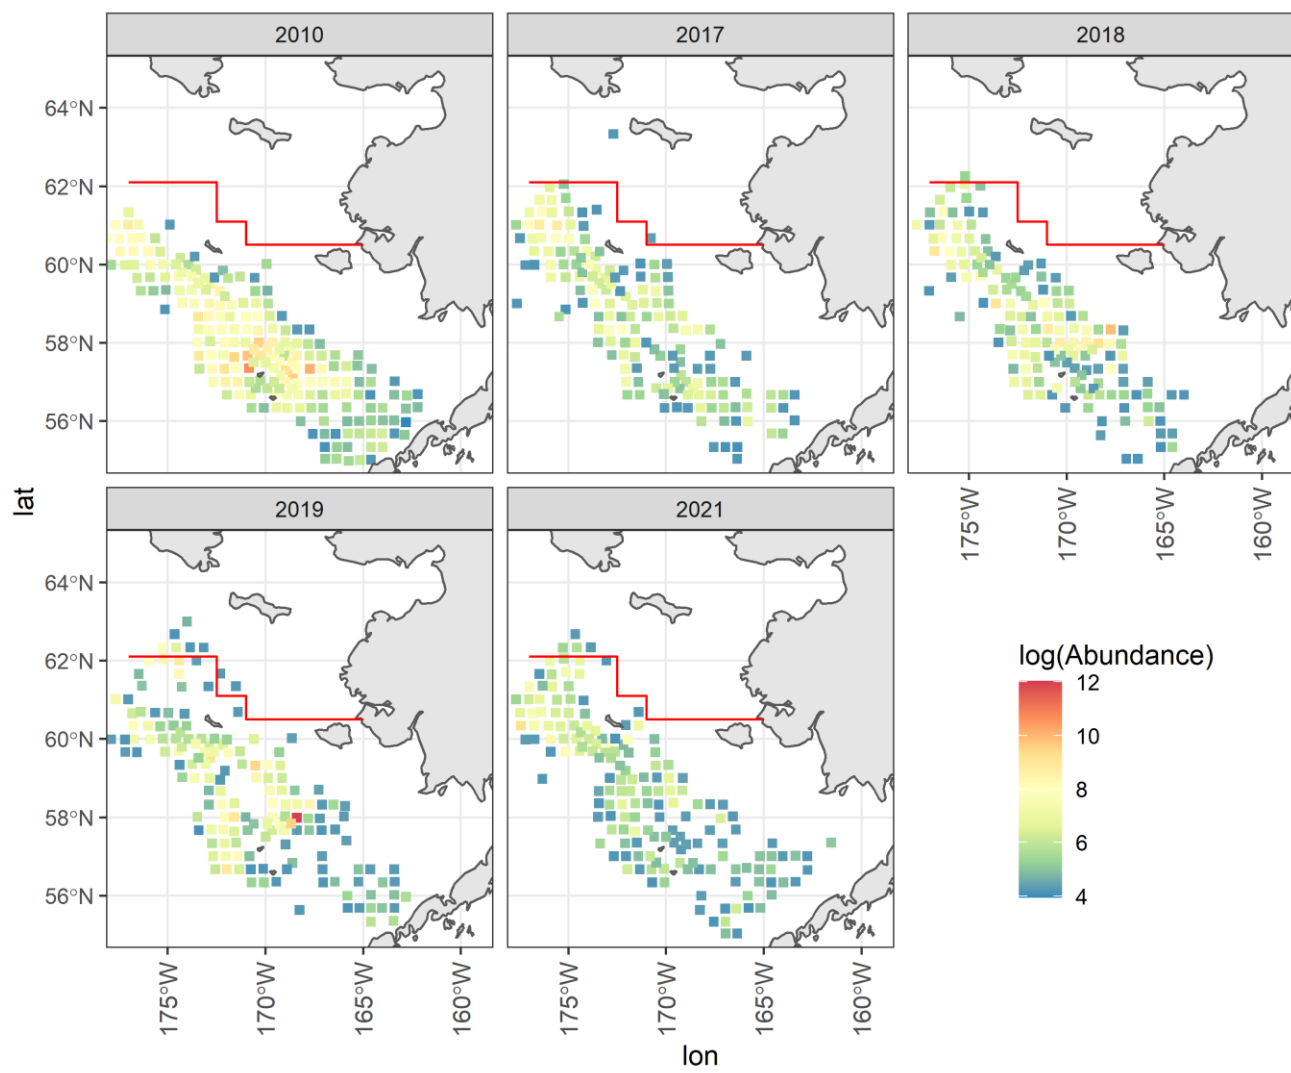

However, 22.1ab does possess undesirable characteristics

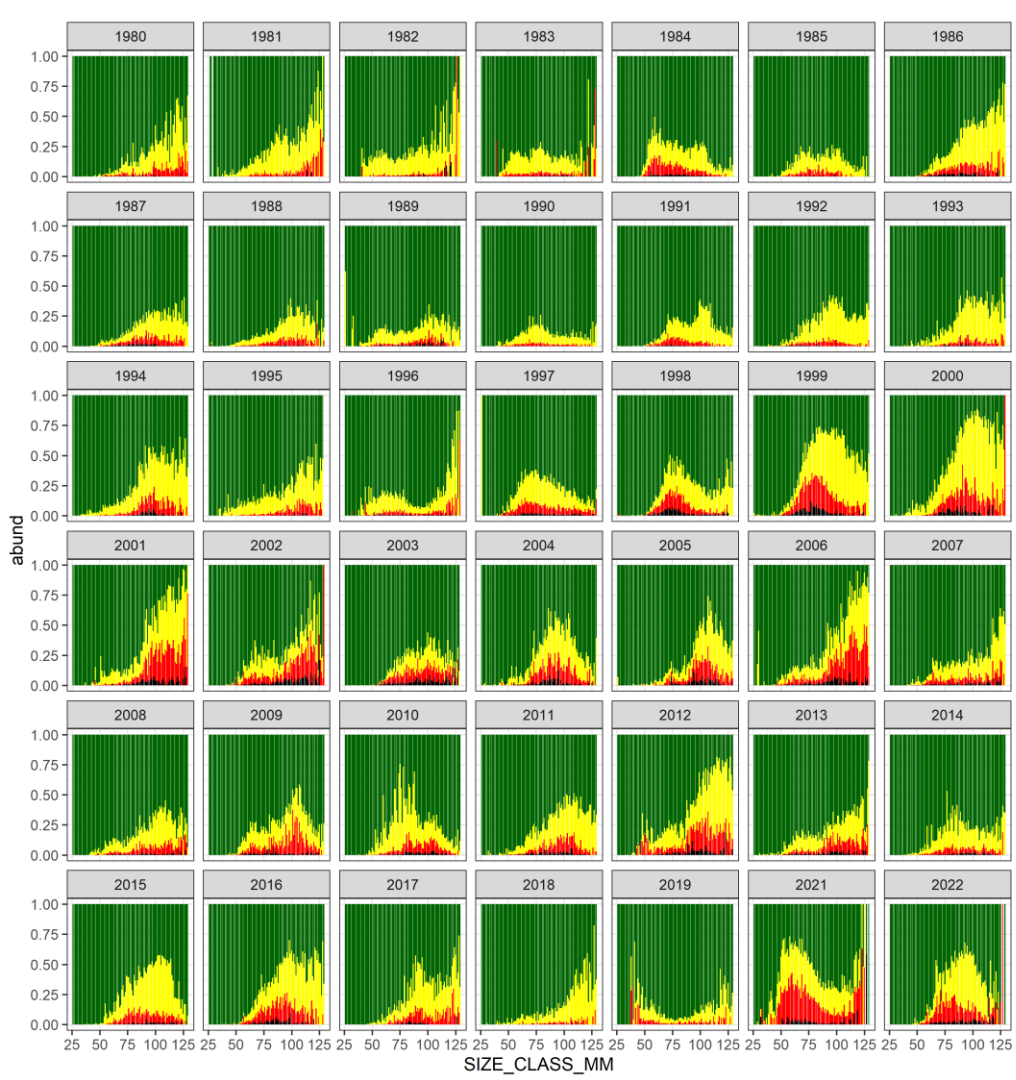

## Tier 4

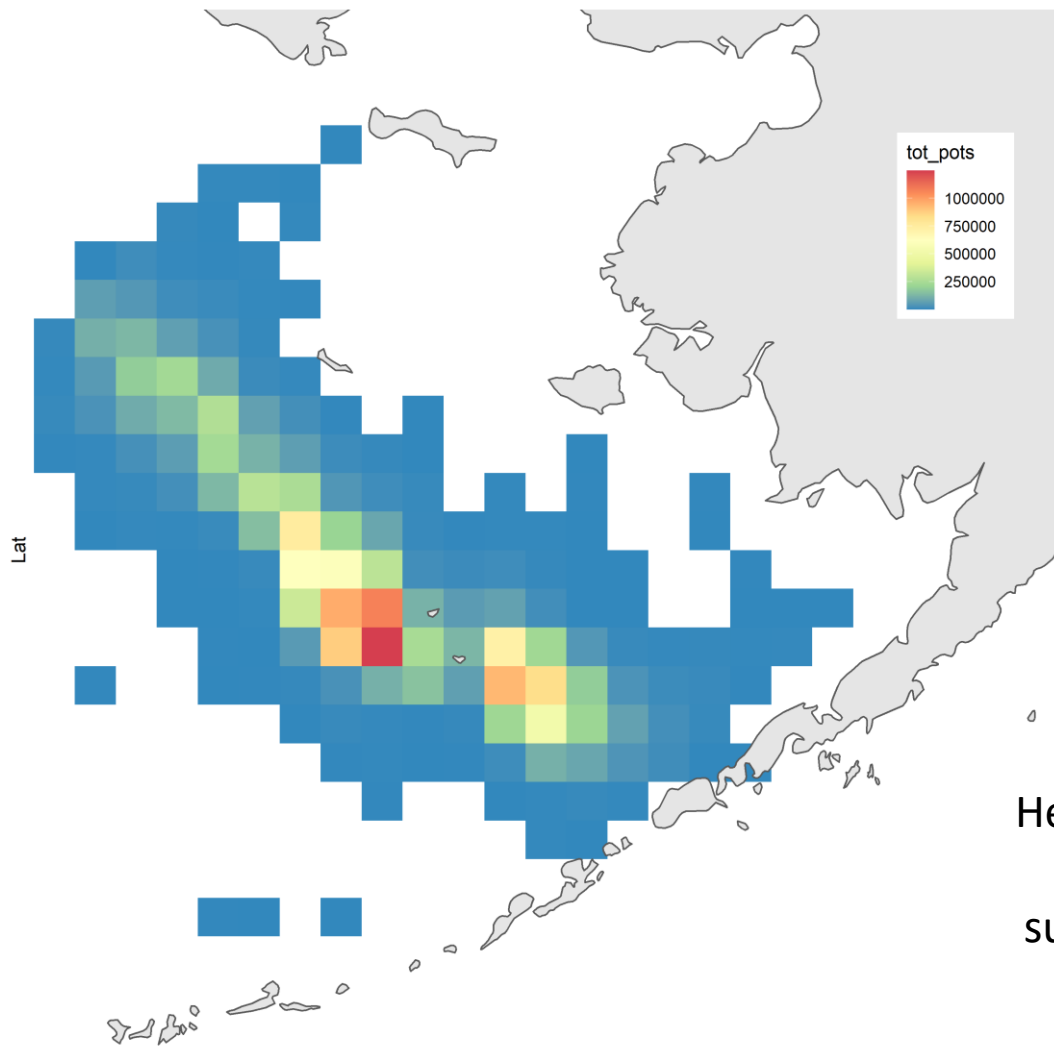

- ‘Current biomass’ should be a proxy for reproductive potential
- BMSY based on 1982-2021
- $FMSY = 0.27 (M)$
- All 4 proxies resulted in a closed fishery

Heatmap of effort in terms of potlifts summed over time.
