# Aleutian Islands Golden King Crab (Lithodes aequispinus) Model-Based Stock Assessment in Spring 2015 

Draft report for the May 2015 Crab Plan Team Meeting

Prepared by:
M.S.M. Siddeek ${ }^{1}$, J. Zheng ${ }^{1}$, and D. Pengilly ${ }^{2}$
${ }^{1}$ Alaska Department of Fish and Game, Division of Commercial Fisheries, P.O. Box 115526, Juneau, Alaska 99811
${ }^{2}$ Alaska Department of Fish and Game, Division of Commercial Fisheries, 351 Research Court, Kodiak, AK 99615

## Executive Summary

## 1. Stock

Golden king crab, Lithodes aequispinus, Aleutian Islands, east of $174^{\circ} \mathrm{W}$ longitude (EAG) and west of $174^{\circ} \mathrm{W}$ longitude (WAG).

## 2. Catches

The Aleutian Islands golden king crab commercial fishery was developed in the early 1980s; the harvest peaked in 1986/87 at 5.900 and 8.800 million pounds, respectively, for EAG and WAG. Catches have been steady since 1996/97 following implementation of total allowable catches (TACs) of 3.000 (EAG) and 2.700 (WAG) million pounds. The TACs were increased to 3.15 and 2.835 million pounds for the two respective regions for the 2008/09 fishery following an Alaska Board of Fisheries (BOF) decision. These levels are below the limit TACs determined under Tier 5 criteria (considering 1991-1995 mean catch as the limit catch) under the new crab management plan. TACs were further increased by another BOF decision to 3.310 million pounds for EAG and 2.980 million pounds for WAG for the 2012/13 fishery. The fishery has harvested close to TAC levels since 1996/97. Catch rates increased in both the EAG and WAG fisheries in the mid-2000s; however, in recent years the WAG catch rates have declined.

## 3. Stock biomass

Estimated mature male biomass (MMB) has decreased following peak levels during the mid-1980s of the directed fishery and then increased and stabilized in recent years for both EAG and WAG. Estimated MMB has decreased during the last few years in the WAG area. The lowest levels of MMB for EAG were observed in early 1990s and MMB systematically increased since 1997. The pattern was similar for WAG with the lowest levels of MMB in 1991 -1992. Stock trends reflected the fishery standardized CPUE trends in both regions.

## 4. Recruitment

The numbers of recruits to the model size groups have shown fluctuating trends for both EAG and WAG. For EAG, the model recruitment was highest in 1990-91, and lowest in 1988 - 1989 while for WAG, the model recruitment was highest in 1992 and 1993 and lowest in 1991 for different scenarios.

## 5. Management performance

The model has not yet been used for making any management decisions.

## 6. Basis for the OFL

We provide the OFL estimates under Tier 4 and Tier 3 approaches for EAG and WAG, respectively.
The length-based model developed for Tier 4 analysis estimates MMB each year for the period February 15, 1986 through February 15, 2014 and projects to February 15, 2015 for OFL and ABC determination. The Tier 4 approach proposes the following OFL and ABCs based on using the 1986-2014 mean MMB as the reference biomass ( $\mathrm{B}_{\text {ref }}$ ). The total OFL and ABC estimates are provided for four scenarios denoted by 2), 3), 7), and 10) in the following four tables:

## EAG (Tier 4):

Biomass, total OFL, and ABC in million pounds.

| Season | Tier | $B_{\text {ref }}$ | Current MMB | $\begin{gathered} \mathrm{MMB} / \\ \mathrm{MMB}_{\text {ref }} \end{gathered}$ | $\mathbf{F}_{\text {OFL }}$ | Years to define $B_{\text {ref }}$ | M | OFL | $\begin{gathered} \mathrm{ABC} \\ \left(\mathrm{P}^{*}=0.49\right) \end{gathered}$ | $\begin{gathered} \hline \text { ABC } \\ (0.9 * \mathrm{OFL}) \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2) $2014 / 15$ | 4a | 11.570 | 19.084 | 1.65 | 0.18 | 1986-2014 | 0.18 | 2.593 | 2.580 | 2.334 |
| 3) $2014 / 15$ | 4a | 12.911 | 24.537 | 1.90 | 0.18 | 1986-2014 | 0.18 | 3.414 | 3.392 | 3.073 |
| 7) $2014 / 15$ | 4 a | 12.668 | 21.453 | 1.69 | 0.18 | 1986-2014 | 0.18 | 2.879 | 2.863 | 2.591 |
| 10) $2014 / 15$ | 4a | 12.739 | 20.668 | 1.62 | 0.18 | 1986-2014 | 0.18 | 2.765 | 2.750 | 2.489 |

Biomass in 1000 t ; total OFL and ABC in t .

| Season | Tier | $\mathrm{B}_{\text {ref }}$ | Current <br> MMB | $\begin{gathered} \mathrm{MMB} / \\ \text { MMB }_{\text {ref }} \end{gathered}$ | $\mathbf{F}_{\text {OFL }}$ | Years to define $B_{\text {ref }}$ | M | OFL | $\begin{gathered} \mathrm{ABC} \\ \left(\mathrm{P}^{*}=0.49\right) \end{gathered}$ | $\begin{gathered} \mathrm{ABC} \\ (0.9 * \mathrm{OFL}) \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2) $2014 / 15$ | 4 a | 5.248 | 8.657 | 1.65 | 0.18 | 1986-2014 | 0.18 | 1176.062 | 1170.062 | 1058.456 |
| 3) $2014 / 15$ | 4 a | 5.856 | 11.130 | 1.90 | 0.18 | 1986-2014 | 0.18 | 1548.717 | 1538.629 | 1393.845 |
| 7) $2014 / 15$ | 4 a | 5.746 | 9.731 | 1.69 | 0.18 | 1986-2014 | 0.18 | 1305.918 | 1298.741 | 1175.326 |
| 10) $2014 / 15$ | 4a | 5.778 | 9.375 | 1.62 | 0.18 | 1986-2014 | 0.18 | 1254.294 | 1247.373 | 1128.865 |

## WAG (Tier 4):

Biomass, total OFL, and ABC in million pounds.

| Season | Tier | Bref | Current MMB | $\begin{gathered} \mathrm{MMB} / \\ \text { MMB }_{\text {ref }} \end{gathered}$ | $\mathrm{F}_{\text {OFL }}$ | $\begin{gathered} \text { Years to } \\ \text { define } B_{\text {ref }} \end{gathered}$ | M | OFL | $\begin{gathered} \mathrm{ABC} \\ \left(\mathrm{P}^{*}=0.49\right) \end{gathered}$ | $\begin{gathered} \mathrm{ABC} \\ (0.9 * \mathrm{OFL}) \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2) $2014 / 15$ | 4b | 9.386 | 7.866 | 0.84 | 0.175 | 1986-2014 | 0.18 | 1.141 | 1.126 | 1.027 |
| 3) $2014 / 15$ | 4 b | 10.378 | 9.007 | 0.87 | 0.175 | 1986-2014 | 0.18 | 1.329 | 1.311 | 1.196 |
| 7) $2014 / 15$ | 4 b | 10.591 | 8.481 | 0.80 | 0.165 | 1986-2014 | 0.18 | 1.134 | 1.119 | 1.021 |
| 10) $2014 / 15$ | 4 b | 10.826 | 9,731 | 0.90 | 0.179 | 1986-2014 | 0.18 | 1.392 | 1.375 | 1.253 |

Biomass in 1000 t; total OFL and ABC in t .

| Season | Tier | $B_{\text {ref }}$ | Current <br> MMB | $\begin{aligned} & \mathrm{MMB} / \\ & \text { MMB }_{\text {ref }} \end{aligned}$ | $\mathrm{F}_{\text {OFL }}$ | Years to define $B_{\text {ref }}$ | M | OFL | $\begin{gathered} \mathrm{ABC} \\ (\mathrm{P} *=0.49) \end{gathered}$ | $\begin{gathered} \mathrm{ABC} \\ (0.9 * \mathrm{OFL}) \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2) $2014 / 15$ | 4b | 4.257 | 3.568 | 0.84 | 0.175 | 1986-2014 | 0.18 | 517.429 | 510.888 | 465.686 |
| 3) $2014 / 15$ | 4 b | 4.707 | 4.085 | 0.87 | 0.175 | 1986-2014 | 0.18 | 602.897 | 594.636 | 542.607 |
| 7) $2014 / 15$ | 4 b | 4.804 | 3.847 | 0.80 | 0.165 | 1986-2014 | 0.18 | 514.482 | 507.771 | 463.034 |
| 10) $2014 / 15$ | 4 b | 4.911 | 4.414 | 0.90 | 0.179 | 1986-2014 | 0.18 | 631.286 | 623.911 | 568.157 |

The Tier 3 approach as an alternative to Tier 4 provides additional sets of OFL estimates based on the mean number of recruits for the period 1986 to 2014 in the following four tables for EAG and WAG, respectively. Either $\mathrm{F}_{35}$ can be used as a multiplier of M if a Tier 4 approach is to be strictly followed or it can be used as it is by promoting the assessment to Tier 3. Assuming M as the $\mathrm{F}_{\text {of }}$ value under Tier 4 approach seems to be more conservative, especially for the WAG stock.

## EAG (Tier 3):

Biomass, total OFL, and ABC in million pounds.

| Season | Tier | $\mathbf{B}_{35}$ | Current <br> MMB | MMB/ $B_{35}$ | $\mathbf{F}_{\text {OFL }}$ | Years to define Bref | $\mathrm{F}_{35}$ | OFL | $\begin{gathered} \mathrm{ABC} \\ \left(\mathrm{P}^{*}=0.49\right) \end{gathered}$ | $\begin{gathered} \mathrm{ABC} \\ (0.9 * \mathrm{OFL}) \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2) $2014 / 15$ | 3a | 14.667 | 17.824 | 1.22 | 0.39 | 1986-2014 | 0.39 | 5.120 | 5.094 | 4.608 |

## 7. Probability density functions of OFL

Assuming a lognormal distribution of total OFL, we determined the cumulative distributions of OFL and selected the median as the OFL.

## 8. The basis for the ABC recommendation

See the ABC section

## 9. A summary of results of any rebuilding analysis:

Not applicable.

## A. Summary of Major Changes

## 1. Changes (if any) to management of the fishery

None.

## 2. Changes to input data

(a) Data update: The 2013/14 commercial fishery retained and total catch, observer nominal total CPUE and fishing effort (pot lifts) to calculate total catches for 1990/91-2013/14, and groundfish discarded catch by size are added. With the availability of additional data, the groundfish bycatch time series is extended back to 1989/90. The commercial retained size frequency and observer sample size frequency data are recalculated weighting by sampled vessel's catch.
(b) New data: EAG male tag-recapture data by size and time at large for 1991, 1997, 2000, 2003, and 2006 releases are considered for the WAG model analysis as well. A limited number of tag recaptures from the WAG area was used in a model scenario for the WAG assessment.
(c) Observer pot sample legal size crab CPUE are standardized by the generalized linear model (GLM) with the negative binomial link function, separately for 1995/96-2004/205 and 2005/06-2013/14 periods (Details in the September 2013 CPT presentation on CPUE standardization).
(d) Fish ticket retained catch CPUE are standardized by the GLM with the additional data (2013/14 fishery) using a lognormal link function considering only the year effect. The 1985-1998 indices are used in the model for scenario 3.

## 3. Changes to assessment methodology

None. The same model has been improved.

## 4. Changes to assessment results

Not applicable because the model has not been used previously.

## B. Response to 2014 CPT comments

The CPT reviewed the model in detail during the September 2014 CPT meeting. So, we present the responses to their comments:

Comment 1: The predicted sample size is generally greater than the input sample size (effective sample size) this may indicate over fitting to the length frequency data. The CPT discussed the weighting of length frequency data, relative abundance index data, and the possibility of using the method of Francis (2011). The CPT recommends the Francis method should be investigated in a model workshop context as this would apply to all crab stock assessments not just Aleutian Golden king crab.

Response: We considered a scenario (11) by iteratively reweighting the input effective sample size. A figure is shown in this document (Figure56).

Comment 2: The better fit to growth data for scenario 5 when the growth matrix is fixed vs. estimated in the model, seems to indicate the model is fitting some other data component at the expense of the growth (tagging) data. A higher weight was put on the total catch likelihood in this assessment to improve fit. There was concern that the fishing mortality values in the early 1990's were too high for the east and west areas. The model estimates more decline in the stock in the early period than indicated by the CPUE time series. There are also very high estimates of discard in 1994 for the WAG and in 1991 and 1992 for EAG. Fits to the length frequency data in the years where total catch was very high shows a distinct lack of fit. This could be due to model initialization or model trying to fit anomalously large total catches.

Response: We considered a scenario (7) where pre 1995 total catches and total catch composition likelihood components are disregarded in the optimization. Indeed this scenario produced better results.

Comment 3: Including a separate molting probability (scenario 2 ) improved the fit of the model compared to scenario 1 . This results in a higher fraction of crab in the diagonal of the growth matrix than can be estimated by a normal distribution.
Scenario 4 estimated lower q for CPUE index and higher biomass than other scenarios. It was not clear why this occurs. The CPT recommends the author do a manual likelihood profile on q to investigate the differences in q estimates.

Response: We provide the manual likelihood profile on $q$ for $E A G$ and $W A G$ in this document (Figures 29 and 55). The CPUE and total negative likelihoods behaved similarly even though the length compositions provided were more influential on the total likelihoods.

Comment 4: Scenarios 6 and 7 (no fishing mortality penalties in any phase) gave same results as scenarios with fishing mortality penalties removed in the last phase. The author doesn't need to include these scenarios in future.

Response: We did not include these scenarios in this report.

Comment 5: Figure 57 retrospective plot appears to be incorrect.
Response: corrected.

The CPT recommendations:

1) Total catch in the early 1990 's for both east and west areas have very large discard estimated relative to other years. Need to check these values to see if they are correct and also are they reliable estimates.

Response: We checked the data and apparently large number of vessels moved to the Aleutian Islands golden king crab area as a result of Bristol Bay red king crab closure.
2) If total catch in early 1990 's is correct however unreliable then run a scenario of the model with total catch time series starting from 1995 to present only.

Response: we ran a scenario (7) excluding the pre-1996/97 period for EAG and pre-1995/96 for WAG.
3) Do sensitivity of initialization of the stock and the fits to the 1990's length frequency data and CPUE data.

Response: We did a sensitivity analysis with an alternative formulation of initial size composition calculator (Quinn and Deriso, 1999). It did not make much difference (scenario 6, table 31).
4) Model run estimating the growth matrix in the model with 1 year tag return data only (instead of scenario 5 which had growth matrix fixed however had a much better fit to growth data then scenario 2).
5)

Response: We considered a scenario with one year tag-recapture data only inside the model (scenario 5, Table 31).
6) There is uncertainty in the scale of biomass (q for the CPUE index). Run the model with fixed values of q and plot all likelihood components vs q .

Response: We did in this report (Figures 29 and 55).
7) Lower weights on likelihoods for length composition data as a sensitivity on the fit to the CPUE data following the method of Francis (2011).

Response: we ran a scenario with iterative re-weighting following Francis (Figure 56).

## C. Introduction

1. Scientific name: Golden king crab, Lithodes aequispinus.
2. Distribution: In Alaska, golden king crab is distributed in the Aleutian Islands, on the continental slope of the eastern Bering Sea, and around the Gulf of Alaska to southeastern Alaska.
3. Evidence of stock structure: There is no direct evidence of separate stock structure in the Aleutian Islands.
4. Life history characteristics relevant to management: There is a paucity of information on golden king crab life history characteristics due in part to the deep depth distribution ( $\sim 200-1000 \mathrm{~m}$ ) and the asynchronous nature of life history events(Otto and Cummiskey 1985, Somerton and Otto 1986). The reproductive cycle is thought to be approximately 24 months in length and at any one time, ovigerous females can be found carrying egg clutches in highly disparate developmental states (Otto and Cummiskey 1985). Females carry large, yolk-rich eggs which hatch into lecithotrophic (non-feeding) larvae that are negatively phototactic (Adams and Paul 1999). Molting and mating are also asynchronous and protracted (Shirley and Zhou 1997, Otto and Cummiskey 1985) with some indications of seasonality (Hiramoto 1985). Molt increment for large males (adults) in Southeast Alaska is 16.3 mm CL per molt (Koeneman and Buchanan 1985), and for legal males in the EAG was estimated at 14.4 mm CL (Watson et al. 2002). Annual molting probability of males decreases with increasing size, which results in a protracted inter-molt period and creates difficulty in determining annual molt probability (Watson et al. 2002). Male size-at-maturity varies among stocks (reviewed by Webb 2014) and declines with increasing latitude from about 130 mm CL in the Aleutian Islands to 90 mm CL in Saint Matthew Island section (Somerton and Otto 1986). Along with a lack of annual survey data, limited stock-specific life history stock information prevents development of the standard length-based assessment model.
5. Brief summary of management history: Since 1996, the Alaska Department of Fish and Game (ADF\&G) has divided management of the Aleutian Islands golden king crab fishery at $174^{\circ} \mathrm{W}$ longitude (ADF\&G 2002). Hereafter, the east of 174 ${ }^{\circ} \mathrm{W}$ longitude stock segment is referred to as EAG and the west of $174^{\circ} \mathrm{W}$ longitude stock segment is referred to as WAG. The stocks in the two areas are managed with a constant annual guideline harvest level or total allowable (retained) catch ( 3.000 million pounds for EAG and 2.700 million pounds for WAG). In 2008, however, the total allowable catch was increased by the BOF decision to 3.150 and 2.830 million pounds for EAG and WAG, respectively (an approximately $5 \%$ increase in TAC). Additional management measures include a
male-only fishery and a minimum legal size limit (152.4 mm CW or approximately 136 mm CL ), which is at least one annual molt increment larger than the $50 \%$ maturity length of 120.8 mm CL for males (Otto and Cummiskey, 1985). Daily catch and catch-per-unit effort (CPUE) are determined in-season to monitor fishery performance and progress towards the TAC. Figures 1 to 5 provide the time series of catches, CPUE, and the geographic distribution of catch during recent fishing seasons. Increases in CPUE were observed beginning in 2000 and again with the implementation of crab rationalization in 2005. This is likely due to changes in gear (crab fishermen, personal communication, July 1, 2008), increased soak time (Figure 6), and decreased competition from the reduced number of vessels fishing. Decreased competition could allow crab vessels to target only the most productive fishing areas. In 2012, a BOF decision increased the TAC levels to 3.31 million pounds for EAG and 2.98 million pounds for WAG for the 2012/13 fishery.

## D. Data

1. Summary of new information:
a. Data are updated by adding the 2013/14 commercial fishery retained and estimated total catch by size, observer CPUE, and male groundfish discard catch by size to the time series. Following the new groundfish bycatch data dump we recalculated the whole time series of groundfish bycatch data which extends back to 1989/90. As a result a number of data points have changed.
b. New data are added by including male tag-recapture data by size and time at large for 1991, 1997, 2000, 2003, and 2006 releases. The tagging experiments were conducted in the EAG area. However, following one of the CPT suggestions, we used the same tagging data for the EAG and WAG modeling. We also considered a limited tag-recapture data from WAG that were released in the 1980s. We did not mix the two sets of data.
2. Available catch and tagging data.

| Data set | Years | Data type(s) |
| :---: | :---: | :---: |
| Retained pot catch | 1985/86-2013/14 | Catch by length |
| Total pot catch | 199091-2013/14 | Catch by length (Observer nominal total CPUE with effort were used to estimate total pot catch) |
| Groundfish discarded catch | 1989/90-2013/14 | Catch by length |
| Observer legal size crab CPUE | 1995/96-2013/14 | Independent estimated annual CPUE index with standard error (by negative binomial GLM) (Fox and Weisberg 2011) |
| Pot Fishery retained catch CPUE | 1985/86-1998/99 | Independently estimated annual CPUE index with standard error considering only the year effect (by lognormal GLM). This series is used in the model only for scenario 3 |
| Tag-recapture data | $\begin{aligned} & \text { EAG: 1991, } \\ & \text { 1997, 2000, } \\ & 2003,2006 \\ & \text { WAG: } 1980 \mathrm{~s} \end{aligned}$ | Release-recapture length and time-at-large - 1717 records <br> - 65 records |

a. A time series of retained and total catch, groundfish fishery discard mortality, and pot fishery effort (Table 1 for EAG and Table 16 for WAG).
b. Time series of pot fishery and observer nominal retained and total CPUE, observer sample size, and estimated observer CPUE index (Table 2 for EAG and Table 17 for WAG).
c. Information on length compositions (Figures $8 \mathrm{a}, \mathrm{b} ; 9 \mathrm{a}, \mathrm{b}$; and 10 a , b for EAG and Figures 31 to 36 for WAG).
d. Survey biomass estimates are not available for the area because no systematic surveys, covering the entire fishing area, have occurred.
f. Other time series data: None.
3. Length-weight relationship: $\mathrm{W}=\mathrm{al}^{?}$ where $\mathrm{a}=2.988 * 10^{-4}, \mathrm{~b}=3.135$.
4. Information on any data sources available, but were excluded from the assessment: None.

## Catch and CPUE data

The commercial catch and length frequency distribution were estimated from Alaska Department of Fish and Game (ADF\&G) landing records and dockside sampling (ADF\&G, 2008, 2011). The annual retained catch, total catch, and groundfish discarded mortality are provided in Table 1 for EAG and Table 16 for WAG. The weighted length frequency data were used to distribute the catch into different (5$\mathrm{mm})$ size intervals. The length frequency data for a year were weighted by the sampled vessel's catch as follows. The $i$-th length-class frequency was estimated as:

$$
\begin{equation*}
\sum_{? ? ? ~ ? ~ ? ~ ? ~}^{\text {? }} \tag{1}
\end{equation*}
$$

where $k=$ number of sampled vessels in an year; $L F Q_{j, i}=$ number of crabs in the $i$-th length-class in the sample from $j$-th vessel. $C_{j}=$ number of crabs caught by $j$-th vessel. Then the relative frequency for the year was calculated and applied to the annual retained catch (in number of crabs) to obtain the catch by length-class.

The annual total catch (in number of crabs) was estimated by the observer nominal total CPUE multiplied by the total fishing effort (number of pot lifts). The weighted length frequency of the observer sample was estimated using Equation 1 and then the relative frequency for the year was calculated. Observer measurement of crab ranged from 20 to 220 mm CL. To restrict the total number of crabs to the model assumed size range (101-185 mm CL), the proportion of observer total relative length frequency corresponding to this size range was multiplied by the total catch (number of crabs). This total number of crabs was distributed into length-classes using the weighted relative length frequency. The size range was further restricted to 101-170+ mm CL for modeling purpose because groundfish bycatch data have a number of zero entries at the 171-185 mm CL range. Note that the total crab catch by size that went into the model did not consider retained and discard components separately.

However, once the model estimated the annual total catch, then retained catch can be deducted from this total and multiplied by an appropriate handling mortality (we used a $20 \%$ handling mortality [Siddeek et al. 2005] to obtain the directed fishery discarded [dead] catch).

Observer data have been collected since 1988 (Moore et al., 2000; Barnard et al., 2001; Barnard and Burt, 2004; Gaeuman, 2011), but data are not comprehensive in the initial years, so a shorter time series of data for the period 1990-2013 was selected for this analysis. Onboard observers count and measure all crabs caught and categorize catch as females, sublegal males, retained legal males, and non-retained legal males in a sampled pot. Annual mean nominal CPUE of retained and total crabs were estimated considering all sampled pots within each season (Tables 2 and 17). For model-fitting the CPUE time series was further restricted to 1995-2013 because the reliability of categorization of crabs by observers improved after 1995. Length-specific CPUE data collected by observers provide information on a wider size range of the stock than does the commercial catch length frequency data obtained from mostly legal-sized landed males.

There were significant changes in fishing practice due to changes in management regulation (e.g., since 1996/97 constant TAC and since 2005/06 crab rationalization), pot configuration (increase in escape web on the pot door to 9 " since 1999), and improvement in observer recording in Aleutian Islands golden king crab fisheries (since 1998). These changes prompted us to consider two sets of catchability and selectivity (total and retained) parameters for the periods 1985-2004 and 2005-2013. To include a long time series of CPUE indices for stock abundance contrast, we also considered the 1985-1998 legal size standardized CPUE as a separate likelihood component in scenario 3. Because of the lack of soak time data previous to 1990, we estimated the CPUE index considering only the year effect by fitting the lognormal GLM to fish ticket data (Tables 3 and 18). For this scenario, we considered three sets of catchability, 1985-1998, 1999-2004, and 2005-2013, but the same two sets of selectivity parameters. For another scenario (scenario 10), we considered three sets of catchability and selectivity.

## E. Analytic Approach

## 1. History of modeling approaches for this stock

The model is under development, and yet to be accepted for OFL and ABC setting.

## 2. Model Description

a. The underlying population dynamics model is male-only and length-based (Appendix A). This model combines commercial retained catch, total catch, groundfish fishery discarded catch, standardized observer legal size catch-per-unit-effort (CPUE) indices, fishery retained catch size composition, total catch size composition, groundfish discard catch size composition, and tag recaptures by release-recapture length to estimate stock assessment parameters.

The data series used in the current assessment for EAG ranges from 1985/86 to 2013/14 for retained catch biomass and size composition; 1995/96 to 2013/14 for standardized legal size crab observer CPUE index; 1985/86 to 1998/99 for standardized legal size crab fish ticket CPUE index; 1990/91 to 2013/14 for total catch biomass and total catch length composition; 1989/90 to 2013/14 for groundfish fishery male bycatch biomass and size composition; and 1991, 1997, 2000, 2003, and 2006 releases and up to 2012 recapture time period for tagging information.

The data series used for the WAG ranges are the same as those for EAG.
b. Software: AD model builder (Fournier et al. 2012).
c. -f . Details are given in Appendix A.
g. Critical assumptions and consequences of assumption failures: We kept $M$ constant at 0.18 , the groundfish selectivity to full selection (selectivity $=1$ ), and discard of legal size males is not considered. These fixed values invariably reduced the number of model parameters to be estimated and helped in convergence. We assumed different $q$ 's (scaling parameter for standardized CPUE in the model) and logistic selectivity patterns for different periods for the pot fishery, 1985 to $<1999$, 1999 to $<2005$ and $>=2005$ under scenario 10. For scenario 3, we assumed three different $q$ 's and two selectivity (pre- and post-rationalization periods) patterns. Because of the lack of an annual stock survey we relied heavily on standardized CPUE indices and catch information to determine the stock abundance trends in both regions. The CPUE standardization followed the GLM fitting procedure (Starr 2012) shown below for EAG and WAG, respectively:

We considered the negative binomial GLM on positive and zero catches to select the explanatory variables. The response variable CPUE is the observer sample catch record for a pot haul. The negative binomial model uses the log link function for the GLM fit. Therefore, we assumed the null model to be
Ú (??? ??) ????? ? ? ?

The maximum set of model terms offered to the stepwise selection procedure was:

?????? ??(? ??? $h_{\text {? }} ? ?$ ? $)$ ? AR??????????? ??,

We used a $\log$ link function and a dispersion parameter $(\theta)$ in the GLM fitting process (September 2013 CPT presentation).

The final models for EAG were:
Ú R?? ? ???? ???? ?????? ??A??? E (forced in) $\theta=1.33$, ??
ǴÉE (4) for the 1995-2004 period,
and
Ú (????) ???? ?????? ??(???? E ) ???? $\theta$ ÉǴ ?? Ç
(5) for the 2005-2013 period.

The final models for WAG were:

(6) for the 1995-2004 period,
and
Ú R??? ???? ??????? ??A? ???h È ??A??? E (forced in)
$\theta=1.2, ?^{\text {ह }} \quad$ C $\quad$ (7) for the 2005-2013 period.

Figures 7 and 30 depict the trends in nominal and standardized CPUE indices for EAG and WAG, respectively.

Standardized nominal CPUE data are presented in Tables 2 and 17 respectively, for EAG and WAG.

We also fitted the lognormal GLM for fish ticket retained CPUE data considering only the year effect for the 1985 to 2013 CPUE series and used the 1985 to 1998 indices with standard errors in the model under scenario 3 (Tables 3 and 18). The lognormal model is:
Ú Æ Ò ? Ö ?
h. Changes to any of the above since the previous assessment: Does not apply for this assessment since the model has not yet been used.
i. Model code has been checked and validated. The code is available from the authors.

## 3. Model Selection and Evaluation

a. Description of alternative model configurations:

We considered eleven similar scenarios for EAG (details are in Table 4) and WAG (details are in Table 19) and presented OFL and ABC results for four preferred scenarios. The four scenarios were:

Scenario 2: Determination of size transition matrix considering logistic pseudo molt probability;

Scenario 3: Determination of size transition matrix considering pseudo molt probability and including the commercial fishery standardized CPUE likelihood component;

Scenario 7: Determination of size transition matrix considering pseudo molt probability and disregarding pre-1996/97 for EAG and pre-1995/96 for WAG total size composition and total catch; and

Scenario 10: Determination of size transition matrix considering logistic pseudo molt probability and including different catchability indices and selectivity for three periods 1985/86-1998/99, 1999/00-2004/05, and 2005/06 - 2013/14.
b. The entire time period $1985 / 86-2013 / 14$ was used to define $B_{\text {current }} / B_{\text {ref }}$ (Tier 4) and the 1986-2014 period was used to define mean number of recruits (Tier 3).
c. Progression of results: Model was not previously used, so, not applicable.
d. Evidence of search for balance between realistic and simpler models: Unlike annually surveyed stocks, Aleutian Islands golden king crab stock biomass is difficult to track and essential biological parameters are assumed based on knowledge from red king crab (e.g., $M$ of 0.18 and pot fishery handling mortality rate of 0.2 ) due to a lack of species/stock specific information. We fixed a number of model parameters after initially running the model with all parameters floated to reduce the number of parameters to be estimated (e.g., groundfish bycatch selectivity parameters were fixed). The eleven scenarios
also considered different configuration of parameters to select the parsimonious models. The detailed results of the preferred four scenarios are provided in tables and figures. The total and retained catch OFL for all the 11 scenarios are provided in Table 31 for their relative merits.
e. Convergence status and criteria: ADMB default convergence criteria.
f. Table of the sample sizes assumed for the size compositional data:

We estimated the input effective sample sizes as $\min \left(0.01^{*}\right.$ observed sample size, N ) for retained catch, $\min (0.001 *$ observed sample size, N$)$ for total catch, and $\min (0.1 *$ observed sample size, N$)$ for groundfish bycatch, where N is the maximum sample size ( 200 for retained catch, 150 for total catch, and 25 for groundfish by catch (see Tables 4 and 19 for details)). We estimated the predicted effective sample size from estimated input effective sample size as follows:

$$
\begin{equation*}
n_{y}=\sum_{l} \hat{P}_{y, l}\left(1-\hat{P}_{y, l}\right) / \sum_{l}\left(P_{y, l}-\hat{P}_{y, l}\right)^{2} \tag{9}
\end{equation*}
$$

where ? ? ? and ? ? ? are estimated and observed size compositions in year $y$ and length class $l$, respectively. We plotted the predicted effective sample sizes against the input effective sample sizes. We used the above formula for iteratively reweighting the effective sample sizes in scenario 11.
g. Do parameter estimates make sense? The estimated parameter values are within the bounds and various plots support that the parameter values are reasonable for a fixed $M$ of 0.18 for this stock.
h. Model selection criteria: We used a number of diagnostic criteria to select the base model over the other model: CPUE fits, observed vs. predicted tag recapture numbers by length class, and catch and bycatch fits. A few figures are provided for the four scenarios in the Results section.
i. Residual analysis: We illustrated residual fits by bubble plots in various figures in the Results section.
j. Model evaluation: Only one model with four scenarios is presented and the evaluations are presented in the Results section below.

## 4. Results

1. List of effective sample sizes and weighting factors:

The maximum effective sample sizes for various scenarios are listed in Tables 4 and 19 respectively, for EAG and WAG. These weights (with the corresponding standard errors) adequately fitted the length compositions and no further changes were examined. The input effective sample sizes vs. predicted effective sample sizes are plotted in Figures 11 and 37 for retained catch, 12 and 38 for total catch, and 13 and 39 for groundfish discard catch for EAG and WAG, respectively. The line passing through the plot is the $1: 1$ line and in most cases the points are equally spread on both sides of the line indicating that the input effective sample sizes are reasonable for the four scenarios. We also provide an example plot showing the result of iteratively weighting of the effective sample sizes for retained catch in the EAG and WAG (Figure 56).

We used weighting factors (corresponding standard errors are included in parentheses) for catch biomass, recruitment deviation, pot fishery F, groundfish fishery F, and tagging (multinomial likelihood). We set the CPUE weights to 1 for all scenarios because additional variance components in the likelihoods should address under-estimation of sampling variance. However, the estimated additional variance values were small for observer CPUE indices, but relatively large for the fish ticket CPUE indices. Nevertheless the CPUE index variances estimated from the negative binomial and lognormal GLMs were adequate to fit the model (parameter estimates: Tables 5 and 6 for EAG and 20 and 21 for WAG for scenarios 2, 3, 7 and 10 , respectively). The numbers of estimable parameters are listed in Table A1 of Appendix A. The weights with the corresponding standard error specifications are detailed in Tables A2a and A2b of Appendix A for EAG and WAG, respectively.
2. Tables of estimates:
a. The parameter estimates with one standard deviation for the scenarios 2,3 , 7, and 10 are summarized respectively in Tables 5 and 6 for EAG and 20 and 21 for WAG. We have also provided the boundaries for parameter searches in those tables, and the estimates were within the bounds. Scenario 1 did not consider the pseudo molt probability function and determined the size transition matrix based on the linear growth increment model with a normal growth variability model. On the other hand, all other scenarios considered pseudo molting probability parameters in addition to the linear growth increment and normal growth variability parameters to determine the size transition matrix.
b. The estimated size transition matrixes for the four scenarios are summarized in Tables 7 to 10 for EAG and in Tables 22 to 25 for WAG. Overall the matrix elements for the four scenarios appear reasonable to describe golden king crab growth.
c. The mature male and legal male abundance time series for the four scenarios are summarized in Tables 11 to 14 for EAG and Tables 26 to 29 for WAG.
d. The recruitment estimates for the four scenarios are summarized in Tables 11 to 14 for EAG and Tables 26 to 29 for WAG.
e. The likelihood component values and the total likelihood values for the four scenarios are summarized in Table 15 for EAG and Table 30 for WAG. Total likelihood values for scenarios 7 and 10 in the two areas are lower but reflect the change in number of parameters.
3. Graphs of estimates:
a. The pre- and post-rationalization periods total and retained selectivity curves for the four scenarios are illustrated in Figure 14 for EAG and Figure 40 for WAG. Total selectivity for the pre-rationalization period was used in the tagging model. The groundfish bycatch selectivity appeared flat in the preliminary analysis indicating that all size groups were vulnerable to the gear. This is also shown in the size compositions of
groundfish bycatch (Figures 10a and 10b, and 35 and 36, for scenarios 7 and 10 , respectively). Thus, we set the groundfish bycatch selectivity to 1.0 for all size-classes in the subsequent analysis.
b. The mature male and legal male biomass time series for the four scenarios are illustrated in Figures 22 and 23 for EAG and in Figures 48 and 49 for WAG. Both legal and mature male biomass trends tracked the CPUE trends well. The GLM-predicted standardized CPUE trends are shown with the mature male biomass figures. We determined the mature male biomass values on 15 February and considered the entire time series for $B_{\text {ref }}$ (for Tier 4 approach) and mean number of recruits (for Tier 3 approach) calculations.
c. The full selection pot fishery F over time for the four scenarios for EAG is shown in Figure 24 and for WAG in Figure 50. The F peaked in 1990s and systematically declined since then in the EAG and generally declined since then in the WAG, but with an increasing trend in the WAG in the recent years.
d. F vs. MMB: We did not provide this figure because the model has not yet been approved.
e. Stock-Recruitment relationship: None.
f. The temporal changes in total number of recruits to the modeled population for the four scenarios are illustrated in Figure 20 for EAG and in Figure 46 for WAG. The recruitment distribution to the model size group (101-170+ mm CL) is shown in Figures 21 and 47 for EAG and WAG, respectively for the four scenarios.
4. Evaluation of the fit to the data:
g. Fits to catches: The fishery retained, total, and groundfish bycatch (observed vs. estimated) plots for the four scenarios are illustrated in Figures 25 to 27 for EAG and 51 to 53 for WAG. All predicted fits were closer to observed values.
h. Survey data plot: We did not consider the pot survey data for the analysis.
i. CPUE index data: The predicted vs. input CPUE indices for the four scenarios are shown in Figure 19 for EAG and Figure 45 for WAG. The four scenarios appear to fit the CPUE indices equally well.
j. Tagging data: The predicted vs observed tag recaptures in length-class for the four scenarios are depicted in Figure 18 for EAG and Figure 44 for WAG. All four scenarios appear to fit tag-recaptures well. Note that we used the EAG tagging information for WAG for all scenarios except one (scenario 4).
k. Molt probability: The predicted molt probabilities vs. CLs for scenario 7 are depicted in Figure 57 for EAG and WAG. The fits appear to be satisfactory.

1. Fit to catch size compositions: Retained, total, and groundfish discard length compositions are shown in Figures 8a, 8b, 9a, 9b, and 10 a, 10b for EAG for the scenarios 7 and 10, respectively, and in Figures 31 to 36 for WAG for scenarios 7 and 10 , respectively. The retained and total catch size composition fits appear satisfactory. We illustrate the standardized residual plots as bubble plots of size composition over time for retained catch (Figures 15 and 41 for EAG and WAG, respectively), for total catch (Figures 16 and 42 for EAG and WAG, respectively), and for groundfish discard catch (Figures 17 and 43 for EAG and WAG, respectively).
m . Marginal distributions for the fits to the composition data: We did not provide this plot in this report.
Plots of implied versus input effective sample sizes and time series of implied effective sample sizes: The input effective sample sizes vs. predicted effective sample sizes are plotted in Figures 11 and 37 for retained catch, 12 and 38 for total catch, and 13 and 39 for groundfish discard catch for EAG and WAG, respectively. The line passing through the plot is the $1: 1$ line and in most cases the points are equally spread on both sides of the line indicating that the input effective sample sizes seem reasonable for the four scenarios.
n. Tables of RMSEs for the indices: We did not provide this table in this report.
o. Quantile-quantile plot: We did not provide this plot in this report.
p. Retrospective and historical analysis: The retrospective fits for the four scenarios are shown in Figure 28 for EAG and in Figure 54 for WAG. The retrospective patterns did not show severe departure when terminal year's data were removed systematically and hence the current formulation of the model appears stable.
2. Uncertainty and sensitivity analysis:
a. The main task was to determine a plausible size transition matrix to project the population over time. We investigated the sensitivity of the model to determine the size transition matrix by using or not using a pseudo molt probability (additional two parameters) function. The model fit is better when the pseudo molt probability sub model is included.

We also determined likelihood values at different $q$ values and plotted component negative likelihood against the $q$ values. It appears that the trend in negative log likelihood of CPUE was similar to that of the total (Figures 29 and 55 for EAG and WAG, respectively).

## F. Calculation of the OFL

Specification of the Tier level:
The Aleutian Islands golden king crab stocks are currently managed under Tier 5 (average catch OFL) control rule. Our analysis attempts to upgrade this stock to the Tier 4 level or possibly to the Tier 3 level. The two Tier level OFL calculation procedures are described below:

## Tier 4 Approach:

1. List of parameters and stock size required by the control rule are:

An average mature male biomass $(M M B)$ for a specified period, $M M B_{r e f}$, current $M M B$; an $M$ value; and a $\gamma$ value.
2. Specification of the total catch OFL:
(a) If $M M B_{t} \geq M M B_{r e f}, \quad F_{O F L}=\gamma M$,
(b) If $M M B_{t}<M M B_{\text {ref }}$ and $M M B_{t}>0.25 M M B_{\text {ref }}$,

$$
\begin{equation*}
F_{O F L}=\gamma M \frac{\left(\frac{M M B_{t}}{M M B_{r e f}}-\alpha\right)}{(1-\alpha)} \tag{10}
\end{equation*}
$$

(c ) If $M M B_{t} \leq 0.25 M M B_{\text {ref }}, F_{O F L}=0$,
where $M M B$ is mature male biomass, $M M B_{r e f}$ is average mature male biomass, and $\gamma$ is a multiplying factor of $M$.

The $O F L$ is estimated by an iterative procedure accounting for intervening total removals (see Appendix A for the formulas).

For the selection of $M M B_{\text {ref }}$, we chose the period from February 15, 1986 to February 15,2014 . This resulted in a $M M B_{\text {ref }}$ range of 5.248 to 5.856 thousand metric tons for EAG and 4.257 to 4.911 thousand metric tons for WAG for the four scenarios. The current $M M B_{2013}$ range was 8.657 to 11.130 thousand metric tons for EAG and 3.568 to 4.414 thousand metric tons for WAG for the four scenarios, resulting in an $F_{O F L}$ of 0.18 for EAG and slightly less for WAG. The total OFL for EAG ranged 1.176 to 1.548 thousand metric tons and 0.517 to 0.631 thousand metric tons for WAG for the four scenarios. The $\gamma$ value was set to 1.0 and an $M$ value of 0.18 was used for $O F L$ calculation (see tables in the Executive Summary).
3. Specification of the retained catch portion of the total catch OFL:

We applied the $F_{O F L}$ with retained selectivity to calculate the retained catch portion of the total catch OFL. The retained catch OFLs for EAG ranged from 1,127 to $1,487 \mathrm{t}$ and that for WAG ranged 475 to 586 t for the four scenarios.
4. Recommendation for $F_{O F L}$, OFL total catch, and the retained catch portion of the OFL for coming year:
EAG: $\mathrm{F}_{\mathrm{OFL}}=0.18$; OFL total catch $=1,306 \mathrm{t}$, retained catch portion of the $\mathrm{OFL}=$ 1251 t (under scenario 7).

WAG: $\mathrm{F}_{\mathrm{OFL}}=0.18$; OFL total catch $=514 \mathrm{t}$; retained catch portion of the $\mathrm{OFL}=$ 475 t (under scenario 7).

## Tier 3 Approach:

We used the model estimated parameter values for the scenarios $2,3,7$, and 10 to calculate $\mathrm{F}_{35}$ reference points. The critical assumptions for reference point estimation are:
a. Natural mortality is constant $(0.18)$ over all 14 size groups.
b. Growth transition matrix is estimated using tagging data with the pseudo molt probability sub-model.
c. The catchability parameter estimate for the 2005/06-2013/14 period is used.
d. Total and retained fishery selectivities are length depended and the 2005/062013/14 period selectivity estimates are used. Groundfish bycatch fishery selectivity is kept constant at 1.0 for all length groups.
e. Model estimated molt probability is not time dependent, but is length dependent.
f. Model estimated recruits (in millions of crabs) are averaged for the time period 1986 to 2014.
g. Model estimated groundfish bycatch mortality values are averaged for the period 2004 to 2013 (10 years).

Method: We simulated the population abundance starting from the model estimated terminal year stock size by length, model estimated parameter values, a fishing mortality value ( F ), and adding a constant number of annual recruits. Once the stock dynamics was stabilized (we used the $99^{\text {th }}$ year estimates) for an $F$, we calculated the MMB/R for that $F$. We computed the relative MMB/R in percentage, ? ? ? ? ? ${ }_{? \AA}$ (where $\mathrm{x} \%=\frac{\frac{? ? ? ?}{?}}{\frac{? ? ? ?}{?}}$ ó È and ? ? ? ? ? is the virgin $M M B / R$ ) for different $F$ values.
$\mathrm{F}_{35}$ is the F value that produces the $\mathrm{MMB} / \mathrm{R}$ value equal to $35 \%$ of ? ? ? ? ?.
$M M B_{35}$ ( or $\mathrm{B}_{35}$ ) is estimated using the following formula:
? ? ? ?? ? ? ? ? ? ? ó ? ? where ? is the mean number of model estimated recruits for a selected period.
?? ?? is determined using Equation 10 replacing ?? by ??? and ? ??? by ???.

Recommendation for $F_{O F L}$, OFL total catch, and the retained catch portion of the OFL for coming year:

EAG: $\mathrm{F}_{\mathrm{OFL}}=0.39$; OFL total catch $=2,579 \mathrm{t}$, retained catch portion of the $\mathrm{OFL}=$ 2,466 t (under scenario 7).

WAG: $\mathrm{F}_{\text {OFL }}=0.28$; OFL total catch $=812 \mathrm{t}$; retained catch portion of the $\mathrm{OFL}=$ 751 t (under scenario 7).

## G. Calculation of the ABC

1. Specification of the probability distribution of the total catch OFL:

We estimated the cumulative probability distribution of OFL assuming a $\log$ normal distribution of OFL. We calculated the OFL at the 0.5 probability and the ABC at the 0.49 probability. The ABC estimate varied for different scenarios,

Under Tier 4 approach, the ABC estimates ranged 1,170 to $1,539 \mathrm{t}$ for EAG and 508 to 624 t for WAG for the four scenarios.

Under Tier 3 approach, the ABC estimates ranged 2,311 to 2,970 t for EAG and 694 to 956 t for WAG for the four scenarios (see the Tables in the executive summary).

## H. Rebuilding Analysis

Not applicable.

## I. Data Gaps and Research Priorities

1. The recruit abundances were estimated from commercial catch sampling data. The implicit assumption in the analysis was that the estimated recruits come solely from the same exploited stock through growth and mortality. The current analysis did not consider the possibility that additional recruitment may occur through immigration from neighboring areas and possibly separate sub-stocks. Extensive tagging experiments or resource surveys are needed to investigate stock distributions.
2. An independent estimate of $M$ is needed for this stock. Tagging is one possibility.
3. An extensive tagging study will also provide independent estimates of molting probability and growth. We used the historical tagging data to determine the size transition matrix.
4. An arbitrary $20 \%$ handling mortality rate on discarded males was used, which was obtained from the red king crab literature (Kruse et al. 2000, Siddeek 2002). An experimentally-based independent estimate of handling mortality is needed for golden king crab.

## J. Acknowledgments

We thank Heather Fitch, Robert Foy, and William Gaeuman, for providing various fisheries data for this assessment; Vicki Vanek and Daniel Urban for providing tagging data ; Leland Hulbert for preparing the catch distribution by ADFG statistical areas; CPT members and industry personnel for various critical questions and modeling guidance; and Joel Webb, William Bechtol, and Chris Siddon for additional editorial review of this document.

Table 1. Time series of annual retained catch (number of crabs), total catch (number of crabs on the deck), pot fishery effort (number of pot lifts), and groundfish fishery discard mortality (number of crabs) (handling mortality rates of $50 \%$ for pot and $80 \%$ for trawl gear were applied, only to the male portion) for the EAG golden king crab stock. The crab numbers are for the size range 101-170+ mm CL. 1985 refers to the 1985/86 fishery. NA: no observer sampling to compute total catch. The directed fishery data include cost-recovery beginning in 2013/14.

| 1997 | 0.585 | 0.043 |
| 1998 | 0.724 | 0.054 |

Table 4. Optimization scenarios considered for the stock assessment model for the eastern Aleutian Islands golden king crab (EAG) stock.

| Scenario |  | Likelihood/Penalty Weights (CV)* | Maximum Effective Sample Size |
| :---: | :---: | :---: | :---: |
| 1 | Commercial fishery retained catch for 1985-2013, total fishery catch for 1990 2013, observer legal size crab CPUE index for 1995-2013, and groundfish bycatch for 1989-2013; $\mathrm{M}=0.18$, pot fishery handling mortality $=0.2$, and ground fish bycatch handling mortality for trawl $=0.8$ and for pot $=0.5$. Tag-release-recapture size data for 1991, 1997, 2000, 2003, and 2006. Size transition matrix was calculated from tagging data by the normal probability function without the molt probability sub-model. Two logistic selectivity models and two catchability coefficients were considered for the pre- and postrationalization periods. Groundfish fishery selectivity was set to 1 . | Retained catch $=500$ (0.032), total catch $=$ 300(0.041), groundfish discard catch $=5(0.324)$, recruitment deviation $=1.5$ (0.629), pot fishery F deviation $($ initial $)=1000$ (0.022) (later relaxed to 0.001(very high)), penalty for regularizing the mean $F$ to $0.35($ initial $)=1000($ later relaxed to 0.001 ), groundfish bycatch fishery $F$ deviation $($ initial $)=1000$ (later relaxed to 0.001 ), tagging data $=1.0(0.805)$, and posfunction $=1000$. | $\begin{aligned} & \text { Retained }=200, \\ & \text { total }=150, \\ & \text { groundfish discard } \\ & =25 \end{aligned}$ |
| 2 | Same as scenario 1, but considered a composite normal and the logistic (molt probability) functions for the size transition matrix calculation. | Same as scenario 1. | Same as scenario 1. |
| 3 | Scenario 2, considered 1985-1998 commercial fishery retained CPUE indices as an additional likelihood component and assumed three catchability coefficients for 1985/861998/99, 1999/00-2004/05, and 2005/06-2013/14 . | Same as scenario 1. | Same as scenario 1. |
| 4 | This scenario pertains to replacing EAG tagging data by the WAG tagging data and not considered for EAG optimization. |  |  |
| 5 | Scenario 2, considered only the first year tagging data to compute the size transition matrix. | Same as scenario 1. | Same as scenario 1. |
| 6 | Scenario 2 with initial size composition estimated using a different formulation to that given in Appendix A (see page 332, Quinn and Deriso, 1999). | Same as scenario 1. | Same as scenario 1. |
| 7 | Scenario 2, considered total catch and length frequency time series from 1996/97 onward in the likelihood functions to avoid unusually high total catches in 1994/95 and 1995/96 seasons. | Same as scenario 1. | Same as scenario 1. |
| 8 | Scenario 2, considered only one catchability coefficient. | Same as scenario 1. | Same as scenario 1. |

| Table 4 continued. |  |  | Same as scenario 1. |
| :---: | :--- | :--- | :--- |
| 9 | Scenario 2, shut off groundfish bycatch, <br> length frequency, and fishing mortality <br> deviation likelihood functions in the <br> minimization and set groundfish F to a <br> minimum of 0.01. | Same as scenario 1. | Same as scenario 1. |
| Scenario 2, considered three logistic <br> selectivity models and catchability <br> parameters for the periods 1985/86- <br> $1998 / 99,1999 / 00-2004 / 05$, and <br> $2005 / 06-2013 / 14$. <br> Same as scenario 2. | Same as scenario 1. | Same as scenario 1. | Iteratively <br> estimated effective <br> sample sizes |

Table 6. Parameter estimates and standard deviations with the 2014 (February 15) MMB for the scenarios 7 and 10 model for the golden king crab data from the EAG, 1985/86-2013/14. A total of 118 and 123 parameters for the two respective scenarios were estimated, but recruitment and fishing mortality deviations and initial size frequency determination parameters were omitted from this list.

Table 11. Annual abundance estimates of model recruits (millions of crabs), legal male biomass with standard deviation $(t)$, and mature male biomass with standard deviation ( t ) for the scenario 2 model for golden king crab in the EAG. Legal male biomass was estimated at the survey time and mature male biomass for year y was estimated on February 15, year y +1 after the year y fishery total catch removal. NA = not available. 1985 refers to the 1985/86 fishery.

| Year | Recruits to the <br> Model ( $\geq 101$ <br> mm CL) | $\begin{gathered} \text { Mature Male } \\ \text { Biomass } \\ (\geq 121 \mathrm{~mm} \mathrm{CL}) \end{gathered}$ | Standard <br> Deviation | Legal Male <br> Biomass ( $\geq$ <br> 136 mm CL ) | Standard <br> Deviation |

Table 12. Annual abundance estimates of model recruits (millions of crabs), legal male biomass with standard deviation $(\mathrm{t})$, and mature male biomass with standard deviation $(\mathrm{t})$ for the scenario3 model for golden king crab in the EAG. Legal male biomass was estimated at the survey time and mature male biomass for year y was estimated on February 15, year $\mathrm{y}+1$ after the year y fishery total catch removal. NA = not available. 1985 refers to the 1985/86 fishery.

Table 16. Time series of annual retained catch (number of crabs), total catch (number of crabs on the deck), pot fishery effort (number of pot lifts), and groundfish fishery discard mortality (number of crabs) (handling mortality rates of $50 \%$ for pot and $80 \%$ for trawl gear were applied, only to the male portion) for the WAG golden king crab stock. The crab numbers are for the size range 101-170+ mm CL. 1985 refers to the 1985/86 fishery.

Table 19. Optimization scenarios considered for the stock assessment model for the western Aleutian Islands golden king crab (WAG) stock.

| Scenario |  | Likelihood/Penalty Weights (CV)* | Maximum Effective Sample Size |
| :---: | :---: | :---: | :---: |
| 1 | Commercial fishery retained catch for 1985-2013, total fishery catch for 1990-2013, observer legal size crab CPUE index for 1995-2013, and groundfish bycatch for 1989-2013; M $=0.18$, pot fishery handling mortality $=0.2$, and ground fish bycatch handling mortality for trawl $=0.8$ and for pot $=0.5$. EAG tag-releaserecapture size data for 1991, 1997, 2000, 2003, and 2006. Size transition matrix was calculated from tagging data by the normal probability function without the molt probability submodel. Two logistic selectivity models and two catchability coefficients were considered for the pre- and postrationalization periods. Groundfish fishery selectivity was set to 1 . | Retained catch $=500(0.032)$, total catch $=300(0.041)$, groundfish discard catch $=$ $5(0.324)$, recruitment deviation $=1.5$ (0.629), pot fishery F deviation $($ initial $)=1000$ (0.022) (later relaxed to 0.001 (very high)), penalty for regularizing the mean F to 0.18 $($ initial $)=1000($ later relaxed to 0.001 ), <br> groundfish bycatch fishery F deviation $=($ initial $)=1000$ (later relaxed to 0.001 ), tagging data $=1.0(0.805)$, and posfunction $=1000(0.022)$ | $\begin{aligned} & \text { Retained }=200, \\ & \text { total }=150, \\ & \text { groundfish discard } \\ & =25 \end{aligned}$ |
| 2 | Same as scenario 1, but considered a composite normal and the logistic (molt probability) functions for the size transition matrix calculation. | Same as scenario 1. | Same as scenario 1. |
| 3 | Scenario 2, considered 1985-1998 commercial fishery retained CPUE indices as an additional likelihood component and assumed three catchability coefficients for 1985/861998/99, 1999/00-2004/05, and 2005/06-2013/14 . | Same as scenario 1. | Same as scenario 1. |
| 4 | Scenario 2, replaced EAG tagging data with the WAG tagging data. | Same as scenario 1. | Same as scenario 1. |
| 5 | Scenario 2, considered only the first year tagging data to compute the size transition matrix. | Same as scenario 1. | Same as scenario 1. |
| 6 | Scenario 2 with initial size composition estimated using a different formulation to that in Appendix A (page 332, Quinn and Deriso, 1999 ). | Same as scenario 1. | Same as scenario 1. |
| 7 | Scenario 2, considered total catch and length frequency time series from 1995/96 onward in the likelihood functions to avoid unusually high total catches in the 1995/96 season. | Same as scenario 1. | Same as scenario 1. |

Table 19 continued

| 8 | Scenario 2, considered only one <br> catchability coefficient. | Same as scenario 1. | Same as scenario <br> 1. |
| :---: | :--- | :--- | :--- |
| 9 | Scenario 2, shut off groundfish <br> bycatch, length frequency, and fishing <br> mortality deviation likelihood <br> functions in the minimization and set <br> the groundfish F to a small value of <br> 0.01. | Same as scenario 1. | Same as scenario <br> 10 |
| Scenario 2 with three logistic <br> selectivity models and catchability <br> parameters for the periods 1985/86- <br> $1998 / 99,1999 / 00-2004 / 05$, and | Same as scenario 1. | Same as scenario <br> 2005/06-201/14. <br> Same as scenario 2. | Same as scenario 1. |

Table 20. Parameter estimates and standard deviations with the 2014 (February 15) MMB for the scenarios 2 and 3 model for the golden king crab data from the WAG, 1985/86-2013/14. A total of 118 and 120 parameters for the two respective scenarios were estimated, but recruitment and fishing mortality deviations and initial size frequency determination parameters were omitted from this list.

## Tag Recaptures, EAG

Figure 18. Observed tag recaptures (open circle) vs. predicted tag recaptures (solid line) by size bin for scenarios (Sc) 2, 3, 7, and 10 fits of EAG golden king crab data.

## EAG CPUE Index

Figure 19. Comparison of input CPUE indices (open circles with 1.96 standard error) with predicted CPUE indices (colored solid lines) for scenarios (Sc) 2, 3, 7 , and 10 fits for EAG golden king crab data, 1995/96-2013/14. Model estimated additional standard error was added to each input standard error.

## EAG Recruits

Figure 20. Estimated number of male recruits (millions of crabs $\geq 101 \mathrm{~mm} \mathrm{CL}$ ) to the golden king crab assessment model for scenarios (Sc) 2, 3, 7, and 10 fits in EAG, 1986-2014.

EAG Recruit Distribution

Figure 21. Recruit distribution to the golden king crab assessment model size group for scenarios (Sc) 2, 3, 7, and 10 fits in EAG.

EAG Mature Male Biomass

Figure 22. Upper panel: Trends in golden king crab mature male biomass for scenarios (Sc) 2, 3, 7, and 10 fits in the EAG, 1985/86-2013/14. Mature male crabs are $\geq 121 \mathrm{~mm}$ CL. Scenario 7 estimates have one standard error confidence limits. Lower panel: GLM predicted standardized CPUE index converted to CPUE in number of crabs per pot lift given as a comparison.

EAG Legal Male Biomass

Figure 23. Trends in golden king crab legal male biomass for scenarios (Sc) 2, 3, 7, and 10 fits in the EAG, 1985/86-2013/14. Legal male crabs are $\geq 136 \mathrm{~mm}$ CL. Scenario 7 estimates have one standard error confidence limits.

## EAG Pot Fishery Total F

Figure 24. Trends in pot fishery full selection total fishing mortality of golden king crab for scenarios (Sc) 2, 3, 7, and 10 fits in the EAG, 19852013 (note: 1985 refers to the 1985/86 fishery).

## Retained Catch, EAG

Figure 25. Observed (open circle) vs. predicted (solid line) retained catch of golden king crab for scenarios (Sc) 2, 3, 7 , and 10 fits in the EAG, 1985-2013. (note: 1985 refers to the1985/86 fishery).

Total Catch, EAG

Figure 26. Observed (open circle starts from 1990) vs. predicted (solid line) total catch of golden king crab for scenarios (Sc) 2, 3, 7, and 10 fits in the EAG, 1985-2013. A handling mortality rate of $20 \%$ was applied to pot discarded catch and it was added to retained catch to get the total catch. (note: 1985 refers to the1985/86 fishery). Predicted total catch time series is extended from 1990/91 to 1985/86.

## GDiscard Catch, EAG

Figure 27. Observed (open circle starts from 1989) vs. predicted (solid line) groundfish discarded catch of golden king crab for scenarios (Sc) 2, 3, 7, and 10 fits in the EAG, 1985-2013. An average handling mortality rate of $65 \%$ (average of $80 \%$ and $50 \%$ ) was applied to groundfish discard. (note: 1989 refers to the 1989/90 fishery). Predicted groundfish discarded catch time series is extended from 1989/90 to 1985/86.

Figure 28. Retrospective fits of the model for removal of terminal year's data for scenarios (Sc) 2, 3, 7, and 10 fits for golden king crab in the EAG, 1985-2013 (note: 1985 refers to the1985/86 fishery).

EAG Negative Log Likelihoods

Figure 29. Total and components negative log-likelihoods vs. fractions of the estimated catchability for scenario 7 fit for golden king crab in the EAG, 19852013 (note: 1985 refers to the1985/86 fishery).

Figure 30. Trends in non-standardized [arithmetic (nominal)] and standardized (negative binomial GLM) CPUE indices with two standard errors of Aleutian Islands golden king crab from WAG (west of $174^{\circ} \mathrm{W}$ longitude). ## Tag Recaptures, WAG

Figure 44. Observed tag recaptures (open circle) vs. predicted tag recaptures (solid line) by size bin for scenarios (Sc) 2, 3, 7, and 10 fits of WAG golden king crab data. The tagging experiments were conducted in EAG.

## WAG CPUE Index

Figure 45. Comparison of input CPUE indices (open circles with 1.96 standard errors) with predicted CPUE indices (colored solid lines) for scenarios (Sc) 2, 3, 7, and 10 fits for WAG golden king crab data. 1995/96-2013/14. Model estimated additional standard error was added to each input standard error.

WAG Recruits

Figure 46. Estimated number of male recruits (millions of crabs $\geq 101 \mathrm{~mm} \mathrm{CL}$ ) to the golden king crab assessment model for scenarios (Sc) 2, 3, 7, and 10 fits in WAG, 1986-2014.

WAG Recruit Distribution

Figure 47. Recruit distribution to the golden king crab assessment model size group for scenarios (Sc) 2, 3, 7, and 10 fits in WAG.

WAG Mature Male Biomass

Figure 48. Upper panel: Trends in golden king crab mature male biomass for scenarios (Sc) 2, 3, 7, and 10 fits in the WAG, 1985/86-2013/14. Mature male crabs are $\geq 121 \mathrm{~mm}$ CL. Scenario 7 estimates have one standard error confidence limits. Lower panel: GLM predicted standardized CPUE index converted to CPUE in number of crabs per pot lift given for comparison.

## WAG Legal Male Biomass

Figure 49. Trends in golden king crab legal male biomass for scenarios (Sc) 2, 3, 7, and 10 fits in the WAG, 1985/86-2013/14. Legal male crabs are $\geq 136 \mathrm{~mm}$ CL. Scenario 7 estimates have one standard error confidence limits.

## WAG Pot Fishery Total F

Figure 50. Trends in pot fishery full selection total fishing mortality of golden king crab for scenarios (Sc) 2, 3, 7, and 10 fits in the WAG, 19852013 (note: 1985 refers to the 1985/86 fishery).

## Retained Catch, WAG

Figure 51. Observed (open circle) vs. predicted (solid line) retained catch of golden king crab for scenarios (Sc) 2, 3, 7, and 10 fits in the WAG, 1985-2013. (note: 1985 refers to the 1985/86 fishery).

Total Catch, WAG

Figure 52. Observed (open circle starting from 1990) vs. predicted (solid line) total catch of golden king crab for scenarios (Sc) 2, 3, 7, and 10 fits in the WAG, 1985-2013. A handling mortality rate of $20 \%$ was applied to pot discarded catch and it was added to retained catch to get the total catch. (note: 1990 refers to the 1990/91 fishery). Predicted total catch time series is extended from 1990/91 to 1985/86.

## GDiscard Catch, WAG

Figure 53. Observed (open circle starts from 1989) vs. predicted (solid line) groundfish discarded catch of golden king crab for scenarios (Sc) 2, 3, 7, and 10 fits in the WAG, 1985-2013. An average handling mortality rate of $65 \%$ (average of $80 \%$ and $50 \%$ ) was applied to groundfish discard. (note: 1989 refers to the1989/90 fishery). Predicted groundfish discarded catch time series is extended from 1989/90 to 1985/86.

Figure 54. Retrospective fits of mature male biomass by the model when terminal year's data were systematically removed until 2008/09 for scenarios (Sc) 2 , 3 , 7, and 10 fits for golden king crab in the WAG, 1985-2013 (note: 1985 refers to the1985/86 fishery).

## WAG Negative Log Likelihoods

Figure 55. Total and components negative log-likelihoods vs. fractions of the estimated catchability for scenario 7 fit for golden king crab in the WAG, 1985-2013 (note: 1985 refers to the 1985/86 fishery).

Figure 56. Predicted effective sample size vs. input calculated effective sample size for retained catch length composition for scenarios 11 fit (iterative estimation of effective sample size following Francis (2011)) to golden king crab data in the EAG and WAG, 1985/96-2013/14.

## Molt Proportion Under Scenario 7

Figure 57. Estimated molt probability vs. carapace length of golden king crab under scenario 7 for EAG (black line) and WAG (green line).

## Appendix A: Integrated model

Aleutian Islands Golden King Crab (Lithodes aequispinus) Stock Assessment Model
Development- East of $174^{\circ} \mathrm{W}$ (EAG) and west of $174^{\circ} \mathrm{W}$ (WAG) Aleutian Island stocks

## Basic population dynamics

The annual [male] abundances by size are modeled using the equation:
where $N_{t, i}$ is the number of [male] crab in length class $i$ on 1 July (start of biological year coinciding with mid survey time) of year $t ; \hat{C}_{t, i}, \hat{D}_{t, i}$, and ??? are respectively the predicted fishery retained, pot fishery discard dead, and groundfish fishery discard dead catches in length class $i$ during year $t ; ?_{?}$ ? ? is estimated from the intermediate total (? ????? ?) catch and the retained (???) catch by the Equation 2c. $X_{i, j}$ is the probability in length-class $i$ growing into length-class $j$ during the year; $y_{t}$ is elapsed time period from 1 July to the mid -point of fishing period in year $t$; and $M$ is instantaneous rate of natural mortality.

The catches are predicted using the equations

$$
\begin{align*}
& \text { ??? } \mathscr{C} \mathbb{A}_{\text {Q ? ? ??? ? }}-? ? ? \tag{2b}
\end{align*}
$$

$$
\begin{align*}
& \text { ??? ??? ? ?? } \tag{2e}
\end{align*}
$$

where $Z_{t, j}$ is total fishery-related mortality on animals in length-class $j$ during year $t$ :
??? ????? ??????
$F_{t}$ is the full selection fishing mortality in the pot fishery, ??? is the full selection fishing mortality in the trawl fishery, ?? ? is the total selectivity for animals in length-class $j$ by the pot fishery during year $t, ? ? ?$ is the selectivity for animals in length-class j by the trawl fishery, ?? ? is the probability of retention for animals in length-class $j$ by the pot fishery during year t .

The initial conditions ( $\mathrm{t}=1985$ ) are computed using the equation $N_{1985, i}=\tilde{N}_{1985} e^{\varepsilon_{i}} / \sum_{j} e^{\varepsilon_{j}}$ where $\tilde{N}_{1985}$ is the total abundance in 1985 , and $\varepsilon_{i}$ are parameters which determine the initial (1985) length-structure (one of $\varepsilon_{i}=0$ to ensure identifiability).

In scenario 6 we used an alternative formulation described on page 332 of Quinn and Deriso (1999).

## Growth

## Molt probability

Growth increment probability with (scenarios 2 and 4 ) and without molt probability (scenarios 1 and 3 ) are used to estimate the size transition matrix using tagging data. Molt probability is assumed to be a logistic function of length,
$? \quad \frac{?}{? ? ?^{? A t_{2} ? ?}}$
where $a$ and $b$ are parameters and $\tau_{i}$ is the mid-point of the contributing length interval $i$.
The expected proportion of molting crabs growing from length class $i$ to length class $j$ during a year, $X_{i, j}$, is:

where $?_{i}$ is the expected growth increment (? ? ? ? ? ? ? , $\omega_{1}, \omega_{2}$, and ? are parameters, and $j_{l}$ and $j_{2}$ are the lower and upper limits of the receiving length interval $j$ (in mm CL), $\tau_{i}$ is the midpoint of the contributing length interval $i$, which is $\ll j$, and $n$ is the total number of receiving length intervals.

## Selectivity and retention

Selectivity and retention are both assumed to be logistic functions of length. Selectivity depends on the fishing period for the pot fishery:
?? $\quad \frac{?}{? ? ? ? ? ? A ? \frac{? ? ? ? ? ?}{? ? ? ? ? ? ?}}$
where $\theta_{95}$ and $\theta_{50}$ are the parameters of the selectivity/ retention pattern (Mark Maunder, unpublished generic crab model). In the program, we re-parameterized the denominator ( $\theta_{95}-\theta_{50}$ ) to $\mathbb{U} R$ ????? so that the difference is always positive.

## Recruitment

Recruitment to length -class i during year t is modeled as? ?? ? ? ?? $\Omega_{\text {? }}$ where $\Omega_{\text {? }}$ is a normalized gamma function

with $\alpha_{r}$ and $\beta_{r}$ (restricted to the first six length- classes).

## Parameter estimation

Table A1 lists the parameters of the model indicating which are estimated and which are prespecified. The objective function includes contributions related to the fit of the model to the available data and penalties (priors on the various parameters).

Tables A2a and A2b list the values for the parameters which weight (with the corresponding standard errors in parentheses) the components of the objective function for EAG and WAG, respectively.

## Likelihood components

## Catches

The contribution of the catch data (retained, total, and groundfish discarded) to the objective function is given by:

$$
\begin{align*}
& L L_{r}^{\text {catch }}=\lambda_{r} \sum_{t}\left\{\ell \operatorname{n}\left(\sum_{j} \hat{C}_{t, j} w_{j}+c\right)-\ell \operatorname{n}\left(\sum_{j} C_{t, j} w_{j}+c\right)\right\}^{2}  \tag{9a}\\
& \text { ??????? ?? } \sum_{?} \text { ? Ú £? ? ? ? ? ? ? - Ú £? ? ? ?? ? ? ? } \tag{9b}
\end{align*}
$$

where $\lambda_{r}, \lambda_{T}$ and $\lambda_{G D}$ are weights assigned to likelihood components for the retained, pot total and groundfish discard catches; $w_{j}$ is the average mass of a crab is size-class $j ; C_{t, j}$,???, and ?? ? ? are, respectively, the observed numbers of crab in size class $j$ for retained, pot total, and groundfish fishery discarded crab during year $t$.

Catch-rate indexes
The catch-rate indices are assumed to be normally distributed about the model prediction. Account is taken of variation in additional to that related to sampling variation:
where $C P U E_{t}^{r}$ is the standardized retain catch-rate index for year $t, \sigma_{r, t}$ is standard error of the logarithm of $C P U E_{t}^{r}$, and ??? ?? is the model-estimate corresponding to $C P U E_{t}^{r}$ :

where $q_{t}$ is the catchability coefficient for year $t, \sigma_{e}$ is the extent of over-dispersion, $c$ is a small constant to prevent zero values ( 0.001 ), and ?????? is the weight assigned to the catch-rate data.

## Length-composition data

The length-composition data are included in the likelihood function using the robust normal for proportions likelihood, i.e. generically:
$L L_{r}^{L F}=0.5 \sum_{t} \sum_{j} \ln \left(2 \pi \sigma_{t, j}^{2}\right)-\sum_{t} \sum_{j} \ln \left[\exp \left(-\frac{\left(P_{t, j}-\hat{P}_{t, j}\right)^{2}}{2 \sigma_{t, j}^{2}}\right)+0.01\right]$
where $P_{t, j}$ is the observed proportion of crabs in size-class $j$ in the catch during year $t, \hat{P}_{t, j}$ is the model-estimate corresponding to $P_{t, j}$, i.e.:

$$
\begin{aligned}
& \text { ??? } \quad \frac{? ? ?}{\sum ? ? ? ?} \\
& \text { ??? } \frac{?_{?} ?}{\sum ? ?} \\
& \text { ??? } \quad \frac{? ? ? ?}{\sum ? ? ? ? ?}
\end{aligned}
$$

$\sigma_{t, j}^{2}$ is the variance of $P_{t, j}$ :

$$
\sigma_{t, j}^{2}=\left[\left(1-P_{t, j}\right) P_{t, j}+\frac{0.1}{n}\right] / S_{t}
$$

$S_{t}$ is the effective sample size for year $t$.
Note: The likelihood calculation for retained length composition starts from length-class 6 (mid length 128 mm CL) because the length-classes 1 to 5 mostly contain zero data.

## Tagging data

Let $V_{j, t, y}$ be the number of males that were released in year $t$ that were in length-class $j$ when they were released and were recaptured after $y$ years, and $\underline{\tilde{V}}_{j, t, y}$ be the vector of recaptures by lengthclass from the males that were released in year $t$ that were in length-class $j$ when they were released and were recaptured after $y$ years. The multinomial likelihood of the tagging data is then:

$$
\begin{equation*}
\ell \mathrm{n} L=\sum_{t} \sum_{j} \sum_{y} \sum_{i} \tilde{V}_{j, t, y, i} \ln \hat{\rho}_{j, t, y, i} \tag{15}
\end{equation*}
$$

where $\hat{\rho}_{j, t, y, i}$ is the proportion in size-class $i$ of the recaptures of males which were released during year $t$ that were in size-class $j$ when they were released and were recaptured after $y$ years:

$$
\begin{equation*}
\underline{\hat{\rho}}_{j, t, y} \propto \underline{s}^{T}[\mathbf{X}]^{y} \underline{\Omega}^{(j)} \tag{16}
\end{equation*}
$$

where $\underline{\Omega}^{(j)}$ is a vector with $V_{j, t, y}$ at element $j$ and 0 otherwise, and ?? is the total selectivity vector (Punt et al. 1997).

This likelihood function is predicted on the assumption that all recaptures are in the pot fishery and the reporting rate is independent of the size of crab. The expected number of recaptures in size-class $l$ is given by:

$$
\begin{equation*}
r_{l}=\sum_{t} \sum_{j} \frac{s_{l}\left[\mathbf{X}^{t}\right]_{j, l}}{\sum_{l^{\prime}} s_{l}\left[\mathbf{X}^{t}\right]_{j, l^{\prime}}} \sum_{k} V_{j, k, t} \tag{17}
\end{equation*}
$$

The last term, $\sum_{k} V_{j, k, t}$, is the numbers recaptured of male crabs that were released in size-class $j$ after t time-steps. The term $\sum_{j} \frac{s_{l}\left[\mathbf{X}^{t}\right]_{j, l}}{\sum_{l^{\prime}} s_{l}\left[\mathbf{X}^{t}\right]_{j, l^{\prime}}} \sum_{k} V_{j, k, t}$ is the predicted number of animals recaptured in length-class $l$ that were at liberty for t time-steps.

## Penalties

Penalties are imposed on the deviations of annual pot fishing mortality about mean pot fishing mortality, annual trawl fishing mortality about mean trawl fishing mortality, recruitment about mean recruitment, average pot fishing mortality about a fixed F value k , and the posfunction :

$$
\begin{align*}
& P_{1}=\lambda_{F} \sum_{t}\left(\ell \mathrm{n} F_{t}-\ell \mathrm{n} \bar{F}\right)^{2}  \tag{18}\\
& P_{2}=\lambda_{F^{T r}} \sum_{t}\left(\ell \mathrm{n} F_{t}^{T r}-\ln \bar{F}^{T r}\right)^{2} \\
& P_{3}=\lambda_{R} \sum_{t}\left(\ell \mathrm{n} \varepsilon_{t}\right)^{2}  \tag{19}\\
& ?_{?} \quad ?_{? ? ?} ? ? \mathrm{~A}-? ?  \tag{20}\\
& ?_{?} \quad ?_{? ? ? ? ?} * ? ? ? ? \tag{22}
\end{align*}
$$

## Standardized Residual of Length Composition

$$
\begin{equation*}
\text { ??? Ç???? } \quad \frac{? ? ? ? ? ? ?}{? ? ? ? ? ?} \tag{23}
\end{equation*}
$$

## Output Quantities

## Harvest rate

Total pot fishery harvest rate:

$$
\begin{equation*}
?_{?} \quad \frac{\sum_{? ? ~ ? ~ ? ~ ? ? ? ~ ? ~ ? ~ ? ~ ? ~ ? ~ ? ~}^{n}}{n} \tag{24}
\end{equation*}
$$

Exploited legal male biomass at the survey time at the start of year $t$ :

$$
\begin{equation*}
L M B_{t}=\sum_{j=\text { legal size }}^{n} s_{j}^{T} s_{j}^{r} N_{j, t} w_{j} \tag{25}
\end{equation*}
$$

where $w_{j}$ is the weight of an animal is length-class j .

Mature male biomass on 15 February spawning time (NPFMC 2007) in the following year:
where $y^{\prime}$ is the elapsed time from 1 July to 15 February in the following year.
For estimating next year limit harvest level from current year stock abundance, a limit $F^{\prime}$ value is needed. Current crab management plan specifies five different Tier formulas for different stocks depending on the strength of information available for a stock, for computing $F^{\prime}$ (NPFMC 2007). For the golden king crab, the following Tier 4 formula is applied to compute $F^{\prime}$ :
(a) If $M M B_{t} \geq M \overline{M B}, \quad F^{\prime}=\gamma M$,
(b) If $M M B_{t}<M \overline{M B}$ and $M M B_{t}>0.25 M \overline{M B}$,

$$
\begin{equation*}
F^{\prime}=\gamma M \frac{\left(\frac{M M B_{t}}{M \bar{M} B}-\alpha\right)}{(1-\alpha)} \tag{27}
\end{equation*}
$$

(c) If $M M B_{t} \leq 0.25 M \bar{M} B, F^{\prime}=0$
where $\gamma$ is a constant multiplier of $M, \alpha$ is a parameter, and $M \bar{M} B$ is the mean mature male biomass estimated for a selected time period and used as a the ? ? ?? ????? for the Tier 4 stock.

Because projected $M M B_{t}$ is depended on the intervening retained and discard catch (i.e., $M M B_{t}$ is estimated after the fishery), an iterative procedure is applied using Equations 26 and 27 with retained and discard catch predicted from Equations $2 b-d$. The next year limit harvest catch is estimated using Equations 2 b -d with the estimated $F^{\prime}$ value.

Table A1. Estimated parameters of the population dynamics model

| Parameter |  |
| :--- | :--- |
| Initial conditions | Number of parameters |
| Initial total numbers, $\tilde{N}_{1985}$ | 1 |
| Length-specific proportions, $\varepsilon_{i}$ | $n-1$ |
| Fishing mortalities |  |
| Pot fishery, $F_{t}$ | $1985-2013$ |
