# NOAA 

## Preliminary assessment of Pacific cod in the Eastern Bering Sea

 FISHERIESAlaska Fisheries
Science Center

Grant Thompson

September 10, 2020

## Team and SSC comments

## Comments on assessments in general

- JPT1: "The Teams recommended that authors continue to fill out the risk tables for full assessments."
- JPT2: "The Teams recommended that adjustment of ABC in response to levels of concern should be left to the discretion of the author, the Team(s), and/or the SSC, but should not be mandated by the inclusion of $\mathrm{>}>1$ level in any particular category."
- SSC1: "The SSC requests that the GPTs, as time allows, update the risk tables for the 2020 full assessments...."
- SSC2: "The SSC recommends dropping the overall risk scores...."
- SSC3: "The SSC requests that the table explanations be included...."
- SSC4: "The SSC discussed whether increased risk or uncertainty was relative to previous assessments of the same stock, or relative to other stocks. Both are relevant and elaboration by the authors or GPTs as to what the elevated risk refers to is encouraged."
- Response: All of these will be addressed in the final version.

## Comments specific to this assessment (1 of 10)

- Note: Given the time constraints posed by this year's meeting schedule, the SSC co-chairs have suggested that authors not feel obligated to respond to all of last year's SSC and Team comments in this year's assessments.
- BPT1: "The Team recommends continuing investigation of the CCDA model averaging method, realizing it is unlikely to be implemented this year. The Team is very enthusiastic about this approach. The Team will discuss with the author whether additional input would be useful in further testing and developing the method." Response: Done.
- SSC5: "The SSC thanks Dr. Thompson for his work on developing the CCDA and supports continued efforts to explore this method. An important feature of this work will be how this method interacts with existing FMP control rules, and specifically how the level of risk aversion chosen (ra term in the loss function) maps onto existing control rule policies. Response: Done (Attachment 2.1.4).

## Comments specific to this assessment (2 of 10)

- BPT2: "A major discussion point was whether all three hypotheses should be retained. Hypothesis \#2, combining the EBS and NBS surveys, was deemed likely given the observations of Pacific cod in the NBS, no evidence of genetic difference, and the presence of age-1 fish throughout the EBS and NBS. Hypothesis \#3 is useful because it admits that dynamics in the NBS may be different than in the EBS. However, the models presented did not capture this possibility and spatial models would be worth investigating. Hypothesis \#1 is the most unlikely hypothesis but ... should be retained at least another year...."
Response: Models consistent with Hypotheses \#2 and \#3 are included in this preliminary assessment, but models consistent with Hypothesis \#1 have been dropped, in part because this hypothesis seems inconsistent with current knowledge regarding stock structure (see SSC7) and also in the interest of reducing the number of models (see BPT5 and SSC10).

## Comments specific to this assessment (3 of 10)

- BPT3: "The Team supported continued research into the abundance and mortality of Pacific cod outside of U.S. waters for inclusion in the stock assessment." Response: Done (courtesy of Cecilia O'Leary).
- BPT4: "The Team recommended using spatio-temporal models for survey data (i.e., VAST with a cold pool covariate and bias correction) and also recommended that the survey team investigate the efficacy of VAST estimates using methods such as cross-validation." Response: As in the ensemble of models included in last year's final assessments, all survey data used in the models presented here are based on the VAST approach, using a cold pool covariate with bias correction, with one exception: Technical issues precluded estimation of the 2019 survey age composition using VAST, so a design-based estimate is used here instead. No new results from cross-validation are available, although efforts are underway to use a "leave-one-out" approach in the next year or two (Jim Thorson, pers. commun.).

## Comments specific to this assessment (4 of 10)

- BPT5: "The Team recommended the $3 \times 3$ factorial design for defining models in the ensemble and feels that the current nine models should be used for management advice. Hypothesis \#1 is the hypothesis under which the assessment has historically operated, and it is useful to carry forward that legacy and retain the historic EBS only assessment. Hypothesis \#3 is useful because it allows for a single stock with different dynamics in the two areas. Although the three models for Hypothesis \#3 did not perform particularly well, this hypothesis is useful and the Team supports further development of models under this hypothesis that may incorporate spatial processes such as migration and differences in growth, for example. All three hypotheses and levels of complexity incorporate features that are of interest and useful for explaining structural uncertainty, but it would be useful to investigate reducing the number of models, such as eliminating one of the hypotheses or one of the levels of complexity." Response: See comment BPT2.

## Comments specific to this assessment (5 of 10)

- BPT6: "The Team recommended retaining all models in the ensemble for this assessment, but to simplify and reduce workload, only report models that are above a cutoff of $1 \%$ weight to represent the base model in the next assessment. This would include five models for comparison next year." Response: In order to address several of the Team and SSC comments, it was necessary to rework the ensemble substantially for this preliminary assessment, and most of the five models referenced in this comment have been dropped.
- BPT7: "The Team recommended organizing the environmental/ ecosystem considerations content of the risk table to those items that are associated with the stock and those that are not (working with ESP and ESR editors may help with this)." Response: This comment will be addressed in the final assessment.

## Comments specific to this assessment (6 of 10)

- BPT8: "The Team recommended a continued investigation into whether a change in growth contributed to the ageing bias fit for 2008 and onward in the complex models as ageing bias and growth may be confounded." Response: All models in this preliminary assessment include time-variability in length at age 1.5, but not in any of the other parameters describing size at age. This issue will likely be among the terms of reference for next year's CIE review, and will be addressed in next year's assessment.
- BPT9: "The Team recommended continued research into the inclusion of fishery age compositions in the models." Response: This will likely be among the terms of reference for next year's CIE review, and will be addressed in next year's assessment (see SSC8).

## Comments specific to this assessment (7 of 10)

- SSC6: "The weighted ensemble was determined using a set of nine criteria with different emphasis factors.... The SSC thought this part of the weighting scheme was transparent and a reasonable step forward. However, the choice of an exponential average instead of the arithmetic average is a much more influential choice than the ad hoc 3:2:1 choice.... The SSC suggested that it may be more transparent to use a more intuitive arithmetic mean...." Response: This preliminary assessment explores the use of cross-conditional decision analysis, which involves two sets of model weights. The first set represents the probabilities that each of the models in the ensemble is the true model, and was computed here as the (rescaled) arithmetic mean of a set of scores, in response to this comment.

## Comments specific to this assessment (8 of 10)

- SSC7: "A major discussion point was whether all three hypotheses should be retained going forward. Hypothesis \#2, combining the EBS and NBS surveys, was considered the most likely given the observations of Pacific cod in the NBS and the lack of genetic differences between these areas. There was general support for removing the models related to Hypothesis \#1 ... altogether, given our understanding of stock structure." Response: Two models consistent with Hypothesis \#2, including Model 19.12, are included in the new ensemble. The new ensemble does not contain any models consistent with Hypothesis \#1.
- SSC8: "The SSC recommends that the authors focus on continuing to improve Model 19.12 and attempt to resolve problems with using fishery age compositions." Response: This preliminary assessment presents an improved method for processing the size composition data that go into Model 19.12. Problems associated with using fishery age compositions will likely be among the terms of reference for next year's CIE review of the assessment by the CIE (see BPT9).

## Comments specific to this assessment (9 of 10)

- SSC9: "The authors should consider whether 19.12 could be 'overfitting...." Response: Half of the models in the new ensemble presented in this preliminary assessment have fewer time-varying parameters than Model 19.12. Also, the use of CCDA should help to mitigate problems of over-parameterization to the extent that it causes a model to perform poorly.
- SSC10: "The SSC recommends that if the authors bring an ensemble model forward in 2021, that it consists of a reduced set of models that still reflect adequate diversity in model structure and hypotheses about stock structure." Response: The ensemble presented in here is smaller, albeit only slightly, than the ensemble used in last year's assessment. Thorough investigation of over-parameterization (see SSC9), inter-area movement/migration (see BPT2, BPT5, and SSC11), and inclusion of both Hypotheses \#2 and \#3 (see BPT2, BPT5, and SSC7) proved to be a difficult task with fewer than 8 models.

NOAAFISHERIES

## Comments specific to this assessment (10 of 10)

- SSC11: "The SSC encourages further investigations into fish movement, both analytically and through tagging studies." Response: Two of the models presented here include analytical treatment of fish movement. Results from tagging studies are summarized (courtesy of Susanne McDermott).
- SSC12: "The SSC requests that the use of VAST, including its assumptions, are clearly documented in next year's assessment." Response: Done (courtesy of Jim Thorson and Jason Conner).
- SSC13: "The SSC notes that development of an ESP for EBS Pacific cod would be advantageous. Given the results of the stock assessments and the vital historic economic, social, and community importance of Pacific cod, the SSC recommends that ... EBS Pacific cod (as well as AI and GOA Pacific cod) be prioritized as new ESPs are developed." Response: Work on ESPs for GOA and EBS Pacific cod began this spring, with draft versions anticipated to be available in time for review in November.

## Models

## Base model (1 of 5)

- Sexes combined
- One season per year
- Natural mortality (constant across age and time) freely estimated
- Mean length at age follows a Richards growth function:
- Base value of length at age 1.5 freely estimated
- With constrained annual deviations on the log scale
- Von Bertalanffy (Brody) growth coefficient freely estimated
- Asymptotic length freely estimated
- Richards growth coefficient freely estimated
- SD of L_at_A varies linearly with L_at_A, parameters freely estimated
- Weight at length varies annually, estimated outside the model
- Maturity at length (constant across time) estimated outside the model

## Base model (2 of 5)

- Mean ageing error varies with age, freely estimated within each block:
- 1977-2007
- 2008-present
- Recruitment is independent of stock size:
- Mean freely estimated within each block:
- Pre-1977
- 1977-present
- With constrained annual deviations on the log scale

## Base model (3 of 5)

- One survey, covering the EBS and NBS combined
- Base value of log catchability freely estimated
- With constrained annual deviations
- Size-based, double-normal selectivity, with parameters as follow:
- Base value of first size with selectivity=1 freely estimated
- With constrained annual deviations on the log scale
- Logit of size range with selectivity=1 fixed at 10.0
- Base value of log of SD for $1^{\text {st }}$ normal pdf freely estimated
- With constrained annual deviations
- Log of SD for $2^{\text {nd }}$ normal pdf fixed at 10.0
- Logit of selectivity at minimum size fixed at -10.0
- Logit of selectivity at maximum size fixed at 10.0

## Base model (4 of 5)

- One fishery, covering the EBS and NBS combined
- Size-based, double-normal selectivity, with parameters as follow:
- First size with selectivity=1 freely estimated
- Logit of size range with selectivity=1 freely estimated
- Base value of log of SD for $1^{\text {st }}$ normal pdf freely estimated
- With constrained annual deviations
- Log of standard deviation for $2^{\text {nd }}$ normal pdf freely estimated
- Logit of selectivity at minimum size fixed at -10.0
- Base value of logit of selectivity at maximum size freely estimated
- With constrained annual deviations

## Base model (5 of 5)

- Input sample sizes (Nsamp) for compositional data range between zero and an initial number (Ninit) according to the formula Nsamp $=$ $(1+\exp (\ln \theta)$ Ninit $) /(1+\exp (\ln \theta))$, where $\ln \theta$ is a timeinvariant parameter (the "Dirichlet-multinomial" parameter, estimated in natural $\log$ space, so that Nsamp approaches 0 as $\ln \theta$ approaches $-\infty$, Nsamp $=(1+$ Ninit $) / 2$ when $\ln \theta=0$, and Nsamp approaches Ninit as $\ln \theta$ approaches $+\infty$ ), freely estimated for each of the compositional data types (fishery size composition data, survey size composition data, and survey age composition data), where:
- For survey compositional data, Ninit is the number of sampled hauls
- For fishery compositional data, Ninit is equal to the number of sampled hauls rescaled so that the average Ninit for the fishery is equal to the average Ninit for the survey (so that, on average, fishery data are emphasized equally with survey data)

## Primary ensemble: factorial design

- Four topics from Team/SSC comments were interpreted as factors:

| Topic | Comment(s) | Binary factor: Does the model... |
| :--- | :--- | :--- |
| M19.12 over-parameterization | SSC9 | ...allow time-varying survey catchability $(Q)$ ? |
| Spatial structure | BPT2 | ...treat the EBS and NBS as separate areas? |
| Hypotheses \#2 and \#3 | BPT2, BPT5, SSC7 | ...use area-specific surveys? |
| Movement | BPT5, SSC11 | ...incorporate explicit inter-area movement? |

- Suggests $2^{4}=16$ models, but note that some combinations are infeasible:
- Separate areas = "no" but movement = "yes" (4 models)
- Separate areas = "yes" but area-specific surveys = "no" (4 models)
- This leaves the following 8 models (color = constrained to be the same):

| Time-varying $Q$ ? | No |  |  |  | Yes |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Separate areas? | No |  | Yes |  | No |  | Yes |  |
| Separate surveys? | No | Yes | Yes |  | No | Yes |  |  |
| Movement? | No |  | No | Yes |  |  | No | Yes |
| Temporary name | A1 | B1 | C1 | D1 | A2 | B2 | C2 | D2 |

- Model A2 is the base model (19.12)

NOAAFISHERIES

## Pri. ensemble: parameterization issues (1 of 2 )

- Two-area models are complicated!
- Require at least one parameter specifying allocation of recruits
- If movement is allowed, require at least seven other parameters
- Movement parameterization in SS described in Attachment 2.1.1
- Two parameters for EBS $\rightarrow$ NBS, two others for NBS $\rightarrow$ EBS
- These define ramps from age 2 to age 7 (first move at age 2)
- If distribution or movement is time-varying, more parameters required
- Tried annual random deviations (failed)
- Instead, deterministic linkage to environmental covariates tried
- For distribution and EBS $\rightarrow$ NBS, sea ice extent fit best
- For NBS $\rightarrow$ EBS, North Pacific Index (NPI) fit best

## Pri. ensemble: parameterization issues (2 of 2 )

- Because no fishery size composition or age composition data are available for the NBS, all NBS fishery selectivity parameters were assumed to "mirror" their base EBS counterparts
- NBS catchability
- As models were being developed, no NBS catch data were available
- For the models that treat the EBS and NBS as separate areas, this made estimation of $\ln (Q)$ for the NBS survey difficult
- Therefore, those models included an informative prior distribution
- More specifically: normal prior with unit variance and mean equal to the point estimate of the EBS survey $\ln (Q)$
- This involved tuning the prior mean iteratively for each such model.
- Although the two models that use area-specific surveys without separate areas appeared to be capable of estimating $\ln (Q)$ without the prior distribution, it was used for those models also

## Primary ensemble: parameter counts

- Counts of parameters, for data through 2019, are as follow:

| Time-varying Q? | No |  |  |  | Yes |  |  |  |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Separate areas? | No |  | Yes |  | No |  | Yes |  |
| Separate surveys? | No | Yes | Yes |  | Yes | Yes |  |  |
| Movement? | No |  | No | Yes | No |  | No | Yes |
| Temporary name | A1 | B1 | C1 | D1 | A2 | B2 | C2 | D2 |
| True parameters | 25 | 30 | 37 | 46 | 25 | 30 | 37 | 46 |
| Annual deviations | 267 | 267 | 267 | 267 | 305 | 343 | 343 | 343 |
| Total parameters | 292 | 297 | 304 | 313 | 330 | 373 | 380 | 389 |

- Counts of "true" parameters are the same in both halves of the table
- Increase L to R within a given half
- Counts of annual devs are equal in $1^{\text {st }}$ half, increase $L$ to $R$ in $2^{\text {nd }}$ half
- Counts of total parameters increase $L$ to $R$ across whole table
- Text contains detailed descriptions of differences between models

## Alternative ensemble

- After the models in the primary ensemble had already been largely developed, a small amount of NBS catch data became available
- This suggested that it might be possible to estimate NBS survey $\ln (Q)$ in the four models that treat the EBS and NBS as separate areas after all
- Prior-less analogues were therefore developed for all six models that used separate surveys (not just the four that used separate areas)
- These six models, together with Models A1 and A2 from the primary ensemble, can be considered to constitute an alternative ensemble
- Note that, when the prior distribution on NBS $\ln (Q)$ is removed from Model B2, it is identical to Model 19.15
- Results in this presentation will focus on the primary ensemble, with a brief set of results for the alternative ensemble

Data

NOAA FISHERIES

## Data used in the models (1 of 4)

- All data are the same as in last year's assessment, except:
- A small change was made in the method used to compile the fishery size composition data
- Used in all models
- NBS catch time series was added
- Used in the four 2-area models
- Time series for a pair of environmental covariates was added
- Used in the two models that incorporate movement
- As in last year's assessment, survey index and age composition data came from VAST runs, but specifications are now explicitly documented, per SSC request

## Data used in the models (2 of 4)

- (New) change in compilation of annual fishery size composition data
- Previously, all year-, month-, area-, and gear-specific size composition were weighted by the respective catch
- Theoretically possible for a small sample size (implying potentially large measurement error) to be associated with a large catch
- Attachment 2.1.2 derives an optimal minimum sample size of 30
- For the overall time series, setting Nmin=30 eliminates $12.1 \%$ of size composition records, but only $0.1 \%$ of the total number of fish measured and only $1.8 \%$ of the total catch
- Rerunning the base model with Nmin=30 resulted in less than a 1\% change in ending spawning biomass

## Data used in the models (3 of 4)

- (New) NBS catch time series

## Data used in the models (4 of 4)

- (New) sea ice extent and NPI, expressed as z-scores

## Preview of data changes in final (1 of 2)

- Environmental covariate time series (existing z-scores will change a bit)
- Sea ice extent z-scores: -2.114 (2019), -0.763 (2020)
- NPI z-scores: 0.245 (2019), 1.284 (2020)
- Size composition
- Fishery size compositions have been updated through August 2020
- Broadly speaking, no surprises
- Mode has been shifting toward larger sizes each of last 3 years
- Few age 2 fish are taken, but some hint of strong 2018 cohort
- NBS survey time series currently includes a record for 2018
- This will likely be dropped, due to unbalanced design

## Preview of data changes in final (2 of 2)

- EBS survey age composition
- The otoliths from the 2019 EBS survey have now been processed
- Technical issues have precluded a VAST estimate of the 2019 age composition, so a design-based estimate will be used for 2019

| Year | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12+ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Data provided for context only (1 of 2)

## - Longline fishery CPUE

U.S. Department of Commerce | National Oceanic and Atmospheric Administration | NOAA Fisheries | Page 32 This information is distributed solely for the purpose of pre-dissemination peer review under applicable information quality guidelines. It has not been formally disseminated by the National Marine Fisheries Service and should not be construed to represent any agency determination or policy.

## Data provided for context only (2 of 2)

- Tagging data were summarized in presentation by Britt and McDermott
- Western Bering Sea (WBS) abundance (courtesy of Cecilia O'Leary)

## Results <br> (primary ensemble except as noted)

## Final model names

- Based on the spawning biomass time series estimates, ADSB values...
- ... $<0.1$ imply minor changes from the base model (19.12), and so get names of the form "19.12x," where x is a letter
- ... $\geq 0.1$ imply major changes from the base model (19.12), and so get names of the form "20.j," where j is a number

## Parameter estimates \& derived series (4 of 17)

- Iteratively tuned $\sigma$ values for annual random deviations (T2.1.5)
- For $\ln ($ Recruits $)$, set $\sigma$ so that var_dev + ave_var $=\sigma^{2}$
- For all others, set $\sigma$ so that var_dev + ave_var $=1$

## Parameter estimates \& derived series (14 of 17)

- Age 0+ biomass time series, combined areas

## Parameter estimates \& derived series (15 of 17)

- Age 0+ biomass time series, separate areas (2-area models only)

## Parameter estimates \& derived series (16 of 17)

- Relative spawning biomass time series, combined areas

## Parameter estimates \& derived series (17 of 17)

- Age 0 recruitment, combined areas

## Performance measures (1 of 5)

- Fit to survey indices (F2.1.7)

NOAAFISHERIES
U.S. Department of Commerce | National Oceanic and Atmospheric Administration | NOAA Fisheries | Page 53 This information is distributed solely for the purpose of pre-dissemination peer review under applicable information quality guidelines. It has not been formally disseminated by the National Marine Fisheries Service and should not be construed to represent any agency determination or policy.

## Performance measures (2 of 5)

- Retrospective plots, 1 -area models (F2.1.8)

Model 19.12a $(\rho=-0.070)$

Model 19.12b ( $\rho=\mathbf{- 0 . 0 8 0}$ )

Model $19.12(\rho=-0.053)$

Model 19.12d ( $\rho=0.025$ )

## Performance measures (3 of 5)

- Retrospective plots, 2-area models (F2.1.8)

Model $20.1(\rho=-0.539)$

Model 19.12c $(\rho=0.100)$

## Performance measures (4 of 5)

- The value of Mohn's $\rho$ for Model 20.3 is heavily influenced by the $10^{\text {th }}$ peel, which will disappear when the final draft is produced
- Bootstrap estimates of the st. dev. and 95\% confidence interval for $\rho$ :

| Statistic | 19.12 a | 19.12 b | 20.1 | 19.12 c | 19.12 | 19.12 d | 20.2 | 20.3 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| mean | -0.070 | -0.079 | -0.539 | 0.100 | -0.053 | -0.025 | -0.109 | 0.466 |
| st. dev. | 0.022 | 0.034 | 0.045 | 0.038 | 0.014 | 0.023 | 0.022 | 0.339 |
| L95\% | -0.116 | -0.146 | -0.615 | 0.027 | -0.081 | -0.074 | -0.150 | 0.028 |
| U95\% | -0.031 | -0.015 | -0.443 | 0.174 | -0.028 | 0.014 | -0.065 | 1.212 |

## Performance measures (5 of 5)

- Goodness of fit summary (T2.1.11)
- For abundance data, ratio = log-scale RMSE / mean(log-scale SE)
- For composition data, ratio = Nsamp / Ninit

| Component | Stat. | Type | Area |  | Ratio of output to input |  |  |  |  |  |  |  |

## Cross-conditional decision analysis

## Introduction to CCDA (1 of 2)

- CCDA was introduced during the September 2019 Team meeting
- Briefly, CCDA is a systematic method for answering a question that regularly plagues attempts to choose a single model from a set of alternatives, namely, "But what if we're wrong?"
- CCDA answers this question by considering not only the performance of a given model within the ensemble when the structure of that model is the "true" one, but also the performance of that model when any of the other models in the ensemble is the "true" one, repeating this process for each model in the ensemble
- Performances are measured by generating a series of bootstrap data sets from each fitted model, then applying each model to each data set and comparing the respective estimates of the quantity of interest to the best estimate from the model that generated the bootstrap data (the "pivot" model)

## Introduction to CCDA (2 of 2)

- Those performances, together with a set of user-specified values representing the subjective probabilities that each of the models in the ensemble is the "true" one, are then used to estimate a set of model weights that optimize the performance of the overall ensemble
- This results in a probability mass function, $p m f$, for the estimated quantity
- Finally, decision theory is then used to obtain an optimal point estimate, given the $p m f$ and a specified level of risk aversion, $r a$, where $r a<0$ implies risk proclivity, $r a=0$ implies risk neutrality, and $r a>0$ represents true risk aversion
- A full description of the steps involved is given in Attachment 2.1.3

## Overview of this application of CCDA

- CCDA was applied here to the primary ensemble for the purpose of developing preliminary estimates of the OFL and ABC for 2021
- Due to time constraints, a fairly small sample of 10 bootstrap data sets was generated from each of the 8 models in the ensemble
- When each of the 8 models was fit to each of the $8 \times 10$ bootstrap data sets, the estimates of 2021 OFL shown in T2.1.18 resulted
- See next slide for an example subset

## Bootstrap estimates

- Example subset of T2.1.18; values are for 2021 OFL (millions of t )

| Pivot | Bootstrap | 19.12 a | 19.12 b | 20.1 | 19.12 c | 19.12 | 19.12 d | 20.2 | 20.3 |

## Model probabilities (1 of 2)

- The probability that any given model in the ensemble is the "true" one was based on scores that were derived from factor-specific formulas that considered the following:
- The extent to which the model structure seems consistent with observed inter-area trends
- Goodness of fit
- Retrospective performance (Mohn's $\rho$ )
- The extent to which the time series of catchability (combined area or by separate areas) deviates from unity

## Model probabilities (2 of 2)

- The details of the formulas are omitted here in the interest of brevity, given that the choice of functional forms was ultimately subjective, but the resulting scores are shown below:

| Model | 19.12 a | 19.12 b | 20.1 | 19.12 c | 19.12 | 19.12 d | 20.2 | 20.3 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Structure | 0.667 | 0.667 | 0.333 | 0.667 | 1.000 | 1.000 | 0.667 | 1.000 |
| Fit | 0.838 | 0.764 | 0.712 | 0.813 | 1.000 | 0.972 | 0.912 | 0.922 |
| Mohn's $\rho$ | 0.956 | 0.947 | 0.598 | 0.927 | 0.972 | 1.000 | 0.920 | 0.643 |
| Catchability | 1.000 | 0.762 | 0.673 | 0.829 | 0.962 | 0.824 | 0.514 | 0.425 |
| Mean | 0.865 | 0.785 | 0.579 | 0.809 | 0.984 | 0.949 | 0.753 | 0.747 |
| Probability | 0.134 | 0.121 | 0.089 | 0.125 | 0.152 | 0.147 | 0.116 | 0.115 |

- The arithmetic mean of the scores was used as the basis for assigning the probabilities (by rescaling so that the values sum to unity), following the recommendation of the SSC (see comment SSC6)
U.S. Department of Commerce | National Oceanic and Atmospheric Administration | NOAA Fisheries | Page 71

## Performance weights (1 of 4)

- An important distinction in CCDA is that the probability of a given model being the "true" one is not necessarily equal to, or even related to, how well that model performs when either it or one of the other models in the ensemble is actually the true model
- The latter concept is represented in CCDA by a vector of model weights (as distinguished from probabilities)
- The model weights are used to form a conditional mean squared error (CMSE) for each pivot model, where the weighted average is computed across models for each bootstrap data set, and then the bootstrapspecific weighted average squared errors are averaged across bootstrap data sets (without weighting, because the bootstrap data sets for a given pivot model are considered to be a random sample)
- T2.1.19 shows example calculations for the equal-weight case
- See next slide for an example subset

## Performance weights (2 of 4)

- Example subset of T2.1.19, where the values in each column labeled by a model number are $1 / 8^{\text {th }}$ of the values in $T 2.1 .8$

## Performance weights (3 of 4)

- The CMSE for a given pivot model describes the performance of the ensemble, conditional on that pivot model being the true model
- Given the CMSE for each pivot model, an ensemble mean squared error is calculated as the sum of the product of the model CMSEs and the model probabilities, which describes the expected (not conditional) performance of the ensemble
- The results for the equal weighting example are shown below:

| Model: | 19.12 a | 19.12 b | 20.1 | 19.12 c | 19.12 | 19.12 d | 20.2 | 20.3 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| probability | 0.1337 | 0.1213 | 0.0895 | 0.1250 | 0.1520 | 0.1467 | 0.1164 | 0.1155 |
| CMSE: | 0.0207 | 0.0015 | 0.0001 | 0.0005 | 0.0215 | 0.0018 | 0.0014 | 0.0002 |
| probability $\times$ CMSE: | 0.0028 | 0.0002 | 0.0000 | 0.0001 | 0.0033 | 0.0003 | 0.0002 | 0.0000 |

- The sum of the values on the bottom row (=0.0067, or -5.0007 on the log scale) is the ensemble MSE when equal weights are used

## Performance weights (4 of 4)

- However, a central feature of CCDA is that the model weights are estimated statistically by minimizing the ensemble MSE
- The model weights estimated in this application are shown below:

| Model | 19.12 a | 19.12 b | 20.1 | 19.12 c | 19.12 | 19.12 d | 20.2 | 20.3 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Weight | 0.000 | 0.012 | 0.000 | 0.244 | 0.000 | 0.060 | 0.000 | 0.684 |

- T2.1.20 shows the results of calculations analogous to those in T2.1.19 when the optimized model weights are used instead of equal weighting
- The CMSE values from T2.1.20 are then multiplied by the model probabilities as shown below:

| Model: | 19.12 a | 19.12 b | 20.1 | 19.12 c | 19.12 | 19.12 d | 20.2 | 20.3 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| probability | 0.1337 | 0.1213 | 0.0895 | 0.1250 | 0.1520 | 0.1467 | 0.1164 | 0.1155 |
| CMSE: | 0.0004 | 0.0010 | 0.0005 | 0.0002 | 0.0006 | 0.0006 | 0.0003 | 0.0002 |
| probability $\times$ CMSE: | 0.0001 | 0.0001 | 0.0000 | 0.0000 | 0.0001 | 0.0001 | 0.0000 | 0.0000 |

- The sum of the values on the bottom row ( $=0.0005$, or -7.6132 on the log scale) is the ensemble MSE when the optimized weights are used

## Model-specific weighted average pmfs (1 of 2)

- For a given pivot model, the OFL estimates in each column of the corresponding section of T2.1.18 can be converted into a scaled histogram, which can then be weighted by the respective performance weight, and then the columns can be summed to generate a conditional weighted average pmf for that pivot model
- These are shown in T2.1.21
- See next slide for an example subset

## Model-specific weighted average pmfs (2 of 2)

- Example subset of T2.1.19

| OFL | Pivot model $=19.12 \mathrm{a}$ |  |  |  |  |  |  |  |  | Pivot model $=19.12 \mathrm{~b}$ |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Overall ensemble pmf

- The model-specific, performance-weighted average pmfs are then weighted by the model probabilities, giving the overall ensemble pmf

## Estimation of OFL and ABC (1 of 2)

- Given this pmf, the only other quantities that need to be specified in order to estimate OFL and ABC in the CCDA approach are the corresponding values of ra
- Because OFL is commonly understood as being a risk-neutral estimate of the fishing mortality rate corresponding to maximum sustainable yield, it seems reasonable to identify $r a=0$ for estimation of OFL
- Because ABC is constrained to be less than OFL, it can be viewed as a risk-averse alternative, but this begs the question of how much risk aversion is appropriate for estimation of ABC (see SSC5)
- For the present application, Attachment 2.1.4 identifies $r a=2$ as a reasonable value for estimation of $A B C$

## Estimation of OFL and ABC (2 of 2)

- Given $r a=0$, the estimate of OFL from CCDA is simply the arithmetic mean of the $p m f$; and given $r a=2$, the estimate of ABC from CCDA is simply the harmonic mean of the pmf
- The arithmetic and harmonic means of the ensemble pmf are $127,119 \mathrm{t}(\mathrm{OFL})$ and $114,101 \mathrm{t}(\mathrm{ABC})$, respectively, representing a buffer of approximately $10 \%$
- Of course, the ABC harvest control rule identified in the BSAI Groundfish FMP still applies, so the CCDA estimate of ABC could be used only if it does not exceed the value resulting from application of that control rule

## Discussion

## Issue 1: structure of final ensemble (1 of 2)

- Two ensembles have been presented here:
- The primary ensemble: 8 models, one of which is M19.12
- An alternative ensemble: same as the primary except that the 6 models that use an informative prior distribution on NBS survey $\ln (Q)$ are replaced by counterparts that lack the prior distribution
- Other options:
- Mix and match from among the ensembles presented
- Replace one or more models in the ensemble with new models
- Forgo an ensemble for this year (at least)
- Perhaps use an ensemble only in years with a CIE review
- Fitting and documenting 8 models in the brief time available for development of the final draft will likely prove to be a challenging undertaking, based on last year's experience with a 9 -model ensemble

## Issue 1: structure of final ensemble (2 of 2)

- Both of the ensembles presented here have the desirable attribute of being based on a factorial design, so eliminating models from either ensemble would remove this attribute unless done carefully
- Minor note: If any of the 2 -area models are to be included in the final draft, experience to date suggests that fixing the value of initial fishing mortality in the NBS fishery at some very small value would likely be of negligible consequence in terms of parameter estimation but would likely result in improved performance in terms of model convergence

## Issue 2: use of CCDA in the final draft

- The main reason to use CCDA in this year's final draft is that it provides a statistically rigorous answer to the "But what if we're wrong?" question
- However, there are several disadvantages as well:
- It is much harder to understand than typical ensemble approaches
- It is currently very time-consuming
- A major impediment: some models have spatial structures that are nested within those of other models
- Even if a CCDA could be conducted in time for this year's final draft, it would be limited to estimation of OFL and ABC
- Use of bootstrap distributions as an approximation of Bayesian posterior distributions is controversial
- Even if the approximation is acceptable in principle, the precision of the pmf based on only 10 bootstraps per model may not be

## PS: An alternative version of M19.12

## Introduction and methods

- At the request of an industry representative, an alternative version of the current base model for EBS Pacific cod (Model 19.12) was run
- In the base model, the base value of catchability $(Q)$ for the trawl survey is estimated freely at 1.034
- In the alternative version, the base value of catchability was fixed at 0.465 , which is the value that sets the average of the product of $Q$ and survey selectivity for fish in the 60-81 cm size range equal to 0.47 , corresponding to the proportion of the population within that size range estimated by Nichol et al. (2007) to be present within the depth range sampled by the survey gear
- The values of the "sigma" terms that constrain the various vectors of annual random deviations were not re-tuned in the alternative version

## Results: impacts on management quantities

- As expected, fixing $Q$ in the manner described has a substantial impact on projections for 2021:
- The estimate of 2021 rel. spawn. biom. increases from 0.30 to 0.60
- i.e., the stock goes from being well below, to well above, the kink in the harvest control rule
- The estimate of $F_{40 \%}$ increases from 0.415 to 0.522
- The estimate of 2021 maxABC increases from 113,071 t to 371,530 t
- Conditional on the 2020 catch being equal to the 2020 ABC

## Results: impacts on objective function

- The alternative version does not fit the data as well (T1):

| Component | Qfree | Qfixed | Change |
| :--- | ---: | ---: | ---: |
| Catch | 0.00 | 0.00 | 0.00 |
| Initial_eq_catch | 0.00 | 0.00 | 0.00 |
| Survey index | -87.65 | -86.31 | 1.34 |
| Size composition | 814.26 | 827.90 | 13.64 |
| Age composition | 251.33 | 273.82 | 22.50 |
| Recruitment | -0.41 | 1.88 | 2.30 |
| Initial_eq_recr | 5.36 | 0.51 | -4.85 |
| Priors | 0.00 | 0.00 | 0.00 |
| Softbounds" | 0.02 | 0.02 | 0.00 |
| Deviations | 97.79 | 99.76 | 1.97 |
| Total | 1080.68 | 1117.58 | 36.90 |

- T2 shows the breakdown of the sizecomp and agecomp components by fleet and year (skipped here in the interest of brevity)

## Results: impacts on main parameters (1 of 2)

- Top part of T3 shows changes in time-invariant parameters that are constrained to be positive (measured as Qfixed/Qfree - 1):

| Parameter | Qfree | Qfixed | Change |
| :--- | ---: | ---: | ---: |
| Natural_mortality | 0.346 | 0.443 | 0.280 |
| L_at_1.5_base | 14.904 | 14.671 | -0.016 |
| L_infinity | 117.310 | 111.147 | -0.053 |
| VonBert_K | 0.108 | 0.111 | 0.029 |
| Richards_coef | 1.467 | 1.550 | 0.056 |
| SD_len_at_1 | 3.511 | 3.582 | 0.020 |
| SD_len_at_20 | 9.860 | 9.169 | -0.070 |
| InitF_main_fsh | 0.133 | 0.049 | -0.634 |
| Main_fsh_sel_PeakStart | 76.012 | 76.011 | 0.000 |
| Main_srv_sel_PeakStart_base | 20.797 | 21.394 | 0.029 |

## Results: impacts on main parameters (2 of 2)

- Bottom part of T3 shows changes in time-invariant parameters that can be either positive or negative (measured as Qfixed - Qfree):

| Parameter | Qfree | Qfixed | Change |
| :--- | ---: | ---: | ---: |
| AgeBias_at_1_1977_2007 | 0.336 | 0.352 | 0.016 |
| AgeBias_at_1_2008_2019 | 0.020 | 0.015 | -0.005 |
| AgeBias_at_20_1977_2007 | 0.907 | 0.835 | -0.072 |
| AgeBias_at_20_2008_2019 | -1.715 | -1.794 | -0.078 |
| ln(Recr_ave_1977_2018) | 13.104 | 14.183 | 1.079 |
| ln(Recr_ave_pre1977_offset) | -0.946 | -0.397 | 0.549 |
| lnQ_main_srv_base | 0.034 | -0.766 | -0.799 |
| Main_fsh_sel_lnSD1_base | 5.976 | 5.965 | -0.011 |
| Main_fsh_sel_lnSD2 | -9.985 | -9.994 | -0.008 |
| Main_fsh_sel_logitEnd_base | 2.006 | 1.548 | -0.459 |
| Main_srv_sel_lnSD1_base | 3.499 | 3.573 | 0.074 |
| lnDM_size_main_fish | 9.990 | 9.990 | 0.000 |
| lnDM_size_main_sur | 9.984 | 9.984 | 0.000 |
| lnDM_age_main_srv | 0.099 | -0.563 | -0.662 |

## Discussion: past uses of Nichol et al. (1 of 3)

- The 2007 and 2008 assessments compared the average product of $Q$ (internally estimated) and selectivity across the 60-81 cm size range against the estimate of 0.47 obtained by Nichol et al. (2007) as one of the model selection criteria
- The 2009 assessment estimated $Q$ iteratively by tuning it so that the average product of $Q$ and selectivity across the $60-81 \mathrm{~cm}$ size range matched the Nichol et al. estimate of 0.47 , giving $Q=0.77$
- The resulting estimate was retained in all assessments through 2015
- The 2016-2020 assessments returned to the practice of freely estimating $Q$, based on comments from the BSAI Team, the SSC, the 2016 CIE review, and the paper by Weinberg et al. (2016)
- Some of relevant excerpts are shown on the next 2 slides

## Discussion: past uses of Nichol et al. (2 of 3)

- BSAI Team minutes, $9 / 15$ : "The fixed survey $Q$ (0.77) based on archival tags ... has become less and less credible as careful experiments and analysis performed by RACE have produced no evidence that cod in the path of the survey trawl avoid capture by any means (e.g., vertical distribution or out-swimming). A higher value of catchability, as estimated by the other models, therefore seems more plausible and prudent."
- SSC minutes, 10/15: "The SSC has been on record encouraging the development of an alternative model that estimates $Q$, due to the very weak or non-existent evidence for net avoidance, which has been corroborated by recent work. This makes the fixed value for $Q$, which was always based on weak evidence, even less tenable than before."

## Discussion: past uses of Nichol et al. (3 of 3)

- CIE reviewer, $4 / 16$ : "It is a mistake to force a given value of $Q$ into the assessment since the assumptions on which the calculations are based are quite different.... It is probably more useful to estimate $Q$ within the model and regard it as a value that reconciles the assessment scale to the survey scale. Fixing $Q$ within the model will add a degree of rigidity that may lead to severely biased estimates of fishing mortality, especially where the catch is treated as a known constant."
- Weinberg et al. (2016): "We agree with Nichol et al. (2007), in that it seems unlikely for the survey trawl to catch $100 \%$ of the Pacific cod in its path $100 \%$ of the time; however, we cast doubt on the conclusion that more than $50 \%$ of large fish swim above the trawl in the presence of trawling activity."
