# Appendix 2.1: <br> Preliminary assessment of the Pacific cod stock in the eastern Bering Sea 

Grant G. Thompson<br>Resource Ecology and Fisheries Management Division<br>Alaska Fisheries Science Center<br>National Marine Fisheries Service<br>National Oceanic and Atmospheric Administration<br>7600 Sand Point Way NE., Seattle, WA 98115-6349

## Introduction

This document represents an effort to respond to comments made by the Joint Team Subcommittee on Pacific cod models (JTS), and the SSC on last year's assessment of the Pacific cod (Gadus macrocephalus) stock in the eastern Bering Sea (EBS, Thompson 2015). Many of those comments were informed by the results of a CIE review of the EBS Pacific cod assessment conducted during February 16-19, 2016. The website located at http://tinyurl.com/Pcod-cie-2016 contains every file vetted during the review process as well as the final reports from the three reviewers.

## Responses to SSC and Plan Team comments on assessments in general

SSC1 (10/15 minutes): "The Team Procedures document clarifies that the proposed development and testing of a naming convention should focus on tracking the modeling configurations used for a particular stock assessment. The rationale for this request is two-fold. First, it will help us understand how long it has been since a benchmark change in model configuration has occurred; second, it will help the reviewers and public to track model changes. Of the options presented in the Joint Plan Teams minutes, the SSC agrees that Option 4 has several advantages and recommends that this Option be advanced next year." As in last year's final assessment, Option 4a was used to number models in this preliminary assessment.

SSC2 (12/15 minutes): "The SSC reminds the authors and PTs to follow the model numbering scheme adopted at the December 2014 meeting." Given that comment SSC1 superseded the model numbering scheme adopted at the December 2014 meeting, it seems reasonable to assume that inclusion of this comment in the $12 / 15$ minutes was an error.

SSC3 (12/15 minutes): "Many assessments are currently exploring ways to improve model performance by re-weighting historic survey data. The SSC encourages the authors and PTs to refer to the forthcoming CAPAM data-weighting workshop report." Results described by Punt (in press) were used to choose a data-weighting method for Model 16.5.

SSC4 (12/15 minutes): "The SSC recommends that assessment authors work with AFSC’s survey program scientist to develop some objective criteria to inform the best approaches for calculating $Q$ with respect to information provided by previous survey trawl performance studies (e.g. Somerton and Munro 2001), and fish-temperature relationships which may impact Q." The recent paper by Weinberg et al. (2016) is an example of the suggested collaboration.

## Responses to SSC and Plan Team comments specific to Eastern Bering Sea Pacific cod

Note: Following the procedure initiated in 2014, the task of developing recommendations for models to be included in this year's preliminary Pacific cod assessments (subject to review and potential revision by the SSC) was delegated to the JTS rather than the full Joint Plan Teams.

SSC5 (12/15 minutes): "The SSC was encouraged by the author’s explanation that dome-shaped selectivity may, in part, be explained by the possibility that some of older fish may be residing in the northern Bering Sea (NBS) at the time of the survey. This is supported by the size composition of the fish in the 2010 NBS trawl survey, which suggested that up to $40 \%$ of the fish in some larger size classes reside in this area, although the overall proportion in the NBS was small. The SSC encourages the author to further examine Pacific cod catches from trawl surveys conducted triennially by the National Marine Fisheries Service (NMFS) (1976-1991) and by the Alaska Department of Fish \& Game (1996 to the present) to monitor the distribution and abundance of red king crab and demersal fish (see: Hamazaki, T., Fair, L., Watson, L., Brennan, E., 2005. Analyses of Bering Sea bottom-trawl surveys in Norton Sound: absence of regime shift effect on epifauna and demersal fish. ICES Journal of Marine Science 62, 1597-1602). While the 2010 bottom trawl survey in the NBS found relatively few Pacific cod ( $3 \%$ of total biomass), it is possible that the proportion of Pacific cod that are outside the standard survey area was higher in other years. A second possibility is that older Pacific cod migrate to nearshore areas to feed in the summer, making them unavailable to the survey." The JTS recommended postponing this examination until 2017, when another survey of the northern Bering Sea is scheduled.

SSC6 (12/15 minutes):"The SSC noted that the iteratively tuned, time-varying parameters in the model have not been updated since 2009. The author confirmed that the currently assumed standard deviations of two dev vectors (log of age-0 recruitment and a parameter corresponding to the ascending part of the selectivity curve) may no longer match the standard deviations of these vectors, which could contribute to retrospective bias. The SSC looks forward to a new paper on this issue that the author is preparing." The paper is in revision following initial journal review.

SSC7 (12/15 minutes):"While the model selection criteria proposed by the author are reasonable, we note that these criteria do not take into account the model fit itself. Model fit and retrospective performance should be more strongly considered in the selection of a final model for specifications." Although selection of a final model is not addressed in this preliminary assessment, retrospective analyses are presented for all models.

SSC8 (12/15 minutes): "Although the SSC has repeatedly stressed the need to incrementally evaluate model changes, the SSC did not intend this to imply an automatic preference for the status quo model (as implied by the authors criterion \#1) if alternatives with better performance are available." This comment will be addressed in the final assessment.

JTS1 (5/16 minutes): "For the BS, the subcommittee recommended that the following models be developed for this year's preliminary assessment:

- Model 1: BS Model 11.5, the final model from 2015 (same as the final models from 2011-2014)
- Model 2: Like BS Model 15.6, but simplified as follows:
o Weight abundance indices more heavily than sizecomps.
o Use the simplest selectivity form that gives a reasonable fit.
o Do not allow survey selectivity to vary with time.
o Do not allow survey catchability to vary with time.
o Force trawl survey selectivity to be asymptotic.
o Do not allow strange selectivity patterns.
o Use empirical weight at age.
- Model 3: Like BS Model 15.6, but including the IPHC longline survey data and other features, specifically:
o Do not allow strange selectivity patterns.
o Estimate catchability of new surveys internally with non-restrictive priors.
o Include additional data sets to increase confidence in model results.
o Include IPHC longline survey, with 'extra SD.'
- Model 4: Like Model 3 above, but including the NMFS longline survey instead of the IPHC longline survey.
- Model 5: Like Models 3 and 4 above, but including both the IPHC and NMFS longline survey data and two features not included in either Model 3 or 4, specifically:
o Start including fishery agecomp data.
o Use empirical weight at age.
- Model 6: Like Model 5 above, but including two features not included in Model 5, specifically:
o Use either Francis or harmonic mean weighting.
o Explore age-specific $M$ (e.g., using Lorenzen function)."
All of the requested models are included in this preliminary assessment (see also comment SSC9). Note that some points in the above lists of features may be somewhat duplicative, but were included by the JTS in order to address specific comments made by CIE reviewers. For Model 6, harmonic mean weighting (Punt in press) and the age-specific natural mortality function proposed by Lorenzen $(1996,2011)$ were used. As noted in the JTS meeting minutes, the model numbers used above were intended just as placeholders, until final model numbers could be assigned, following the adopted model numbering convention (see comment SSC1). Application of the numbering convention resulted in the following model numbers:

| JTS "placeholder" model number: | 1 | 2 | 3 | 4 | 5 | 6 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Final model number: | 11.5 | 16.1 | 16.2 | 16.3 | 16.4 | 16.5 |

JTS2 (5/16 minutes): "For the EBS, the JTS recommended that the following non-model analysis be conducted for this year's preliminary assessment:

- Non-model analysis 1: Verify that the trawl survey data sometimes include age 0 fish."

Although very rare ( 5 records in 1984 and 1 record in 2002), the trawl survey data do sometimes include age 0 fish, as confirmed this summer by AFSC RACE and Age and Growth personnel (pers. commun., Dan Nichol (RACE) and Delsa Anderl (Age and Growth)).

SSC9 (6/16 minutes): "The SSC accepts the JTS recommendations for models to bring forward in the 2016 assessment...." See comment JTS1.

SSC10 (6/16 minutes): "The SSC agrees with CIE recommendations to use all reasonable data sources that are available, although the use of the longline survey data in the model has been attempted in the past with little success. As the author noted, survey indices were generally negatively correlated with model-estimated biomass in past assessments. The use of 'extra SD' in the proposed models for both regions is a reasonable approach to deal with this issue." Internally estimated increments to the logscale standard errors for the IPHC and NMFS longline survey indices are reported in Table 2.1.8.

SSC11 (6/16 minutes): "The SSC encourages the use of empirical weight-at-age data in some of the model variants, but notes that this requires precise aging data." Empirical weight-at-age data are used in

Models 16.1, 16.4, and 16.5. Some issues involved in generating these data are discussed in the "Data" section..

SSC12 (6/16 minutes): "The SSC encourages the author to conduct a retrospective analysis across historically used models in addition to the standard retrospective analysis using the current model." The requested analysis is not included in this preliminary assessment. It may be noted that there have been no changes in the accepted model since 2011. Barring any changes in this request, the analysis will be included in the final assessment.

SSC13 (6/16 minutes):"The SSC encourages further work (outside the model) to examine potential causes for the apparent dome-shaped selectivity in most models. Research on these older 'missing' fish could include analysis of existing northern Bering Sea survey data, as noted in last December's minutes, and an analysis of slope survey data to examine if older fish descend to deeper waters as suggested in public testimony." See comment SSC5.

## Data

The data used in this preliminary assessment are identical to those used in last year's final assessment (Thompson 2015), except for:

- the addition of "empirical" weight-at-age data in Models 16.1, 16.4, and 16.5;
- the addition of IPHC survey data (abundance index and size composition) in Models 16.2, 16.4, and 16.5; and
- the addition of NMFS longline survey data (abundance index and size composition) in Models $16.3,16.4$, and 16.5 .

The following table summarizes the sources, types, and years of data included in the data file for one or more of the stock assessment models (italics denote data not included in last year's assessment):

| Source | Type | Years |
| :--- | :--- | :--- |
| Fishery | Catch biomass | $1977-2015$ |
| Fishery | Catch size composition | $1977-2015$ |
| Fishery | Catch per unit effort | $1991-2015$ |
| Fishery | Empirical weight at age | $2008-2011$ |
| EBS shelf bottom trawl survey | Relative abundance | $1982-2015$ |
| EBS shelf bottom trawl survey | Size composition | $1982-2015$ |
| EBS shelf bottom trawl survey | Age composition | $1994-2014$ |
| EBS shelf bottom trawl survey | Mean size at age | $1994-2014$ |
| EBS shelf bottom trawl survey | Empirical weight at age | $1998-2014$ |
| IPHC longline survey | Relative abundance | $1997-2014$ |
| IPHC longline survey | Size composition | $2008-2009$, 2011-2015 |
| NMFS longline survey | Relative abundance | $1997-2015$ (odd years only) |
| NMFS longline survey | Size composition | $1997-2015$ (odd years only) |

Empirical weight-at-age estimates were computed using a two-stage bootstrap procedure (J. Ianelli, AFSC, pers. commun.) from the available age data, resulting in the values shown in Table 2.1.1. Four possible concerns might be noted with respect to these data:

1. No smoothing was applied to the estimates, even though they exhibit a fair amount of variability. For example, in the set of mid-year survey estimates, $18 \%$ of the cells differ from their respective age-specific time series average by $20 \%$ or more (not counting age 0 ); and in the set of fishery estimates, $34 \%$ of the cells differ from their respective age-specific time series average by $20 \%$ or more (not counting ages 0 or 1 ).
2. Age data exist for only 17 of the 34 years in the survey time series and only 4 of the 39 years in the fishery time series. Long-term averages were used for all years with no age data.
3. The fishery age data come primarily from the longline fishery, and may not be representative of the overall fishery.
4. Because the trawl survey takes place in summer, beginning-of-year population weights at age were calculated by averaging mid-year weight(age,year) and mid-year weight(age-1,year-1), implying that weight at age changes linearly within each one-year interval.

Relative abundance data from the IPHC and NMFS longline surveys are shown in Table 2.1.2, and size composition data from those two surveys are shown in Table 2.1.3.

Because the models presented in this preliminary assessment include various methods for tuning the input sample sizes for size and age composition data (see next section), a review of the current methods for specifying these input sample sizes is presented here: For the 2007 assessment, the harmonic means from a bootstrap analysis of the available fishery length data from 1990-2006 were computed. The harmonic means were smaller than the actual sample sizes, but still ranged well into the thousands. Analysis of the harmonic means revealed that, except when the actual sample size was very small (less than about 400), they tended to be very nearly proportional to the actual sample sizes, with the coefficient of proportionality dependent on whether the data were collected prior to 1999. For the years prior to 1999 the ratio was consistently very close to 0.16 , and for the years after 1998 the ratio was consistently very close to 0.34 . Thus, ever since the 2007 assessment (with some minor modifications through the years), input sample sizes have been set according to the following three-step process. First, records with actual sample sizes less than 400 are omitted. Second, sample sizes for fishery length compositions from years prior to 1999 are tentatively set at $16 \%$ of the actual sample sizes, and sample sizes for fishery length compositions since 1999 and sample sizes for all survey length compositions are tentatively set at $34 \%$ of the actual sample sizes. Third, all sample sizes are adjusted proportionally so that the average is 300 . Age composition input sample sizes are obtained by scaling the number of otoliths read so that the average is 300 .

## Model structures

All of the models presented in this preliminary assessment were developed using Stock Synthesis (SS, Methot and Wetzel 2013). The version used to run all models was SS V3.24u, as compiled on 8/29/2014. Stock Synthesis is programmed using the ADMB software package (Fournier et al. 2012). The user manual for SS V3.24s, along with a "change log" documenting revisions between V3.24s and V3.24u, is available at:
https://drive.google.com/a/noaa.gov/?tab=mo\#folders/0Bz1UsDoLaOMLN2FiOTI3MWQtZDQwOS00Y WZkLThmNmEtMTk2NTA2M2FjYWVh.

## Developing the models requested by the Joint Team Subcommittee

Six models are presented in this preliminary assessment. Model 11.5 has been the accepted model since 2011. The other five models (Models 16.1-16.5) are all variants of Model 15.6, which was introduced in last year's preliminary assessment (where it was labeled "Model 6"). Details of Models 11.5 and 15.6 are described in their respective subsections below. The distinguishing features of Models 16.1-16.5 were
listed above (see comment JPT1 under "Responses to SSC and Plan Team comments specific to Eastern Bering Sea Pacific cod," above).

In the minutes of its May 2016 meeting, the JTS recognized that some of the terms used in the descriptions of its requested models were somewhat subjective and that, in making those requests, the assessment author would need to determine:

1. How to measure the "weight" assigned to abundance indices and size composition data in the same units (Model 16.1).
2. What constitutes a "reasonable fit" to the size/age composition data (Model 16.1).
3. What constitutes a "strange" selectivity pattern (Models 16.1-16.5).

These issues were addressed as follows:

1. The relative "weight" assigned to abundance indices and size composition data was determined by comparing the average spawning biomasses from three models:
A. a model with a specified set of likelihood "emphasis" $(\lambda)$ values, with each $\lambda \geq 1.0$;
B. a model in which $\lambda$ for the abundance data was set equal to 0.01 while each $\lambda$ for the size composition data (fishery and survey) was left at the value specified in model A; and
C. a model in which each $\lambda$ for the size composition data (fishery and survey) was set equal to 0.01 while each $\lambda$ for the abundance data was left at the value specified in model B. Model B was taken to represent model A with the abundance data "turned off," while model C was taken to represent model A with the size composition data "turned off" (a $\lambda$ value of 0.01 rather than 0 was used for to represent "turning off" a data component because some parameters might prove inestimable if that data component were removed entirely). The abundance data in model A were determined to receive greater weight than the size composition data in that model if the absolute value of the proportional change in spawning biomass between models B and A exceeded the analogous value between models C and A. The JTS requested that this criterion (giving greater weight to abundance data than size composition data) be included in Model 16.1 only. As it turned out, the default $\lambda$ value of 1.0 for all data components was sufficient to satisfy this criterion, so no adjustments to any of the $\lambda$ values were necessary.
2. To focus on the ability of a particular functional form to fit the data, independent of the absolute values of the sample sizes specified for the associated multinomial distribution or $\lambda$ values, weighted coefficients of determination $\left(R^{2}\right)$, computed on both the raw and logit scales, were used to measure goodness of fit (the equations below are written in terms of age composition; the equations for size compositions are analogous):
$R^{2}=\sum_{y=y \min }^{y \max }\left(w_{y} \cdot\left(1-\frac{\sum_{a=0}^{a \max }\left(\text { Pobs }_{a, y}-\text { Pest }_{a, y}\right)^{2}}{\sum_{a=0}^{a \max }\left(\text { Pobs }_{a, y}-\text { Pobs }_{a v e, y}\right)^{2}}\right)\right)$,
and

$$
R^{2}=\sum_{y=y \min }^{y \max }\left(w_{y} \cdot\left(1-\frac{\sum_{a=0}^{a \max }\left(\operatorname{logit}\left(\operatorname{Pobs}_{a, y}\right)-\operatorname{logit}\left(\text { Pest }_{a, y}\right)\right)^{2}}{\sum_{a=0}^{a m a x}\left(\operatorname{logit}\left(\operatorname{Pobs}_{a, y}\right)-\operatorname{logit}\left(\text { Pobs }_{a v e, y}\right)\right)^{2}}\right)\right)
$$

where

$$
w_{y}=\frac{n_{y}}{\sum_{i-v \min }^{\max } n_{i}}
$$

Pobs $_{a, y}$ represents the observed proportion at age $a$ in year $y$, Pobs $_{\text {ave, } y}$ represents the average (across ages) observed proportion in year $y$, Pesta,y represents the estimated proportion at age $a$ in year $y$, and $n_{y}$ represents the specified multinomial sample size in year $y$. To guard against the possibility of achieving misleadingly high $R^{2}$ values by extending the size or age range beyond the sizes or ages actually observed, the data were filtered by removing all records with Pobs ${ }_{a, y}<$ 0.001 prior to computing the $R^{2}$ values. A fit was determined to be "reasonable" if it yielded both an $R^{2}$ value of at least 0.99 on the raw scale and an $R^{2}$ value of at least 0.70 on the logit scale. As with \#1 above, the JTS requested that this criterion (simplest selectivity function that gives a reasonable fit) be included in Model 16.1 only. Because the "random walk with respect to age" selectivity function gave a reasonable fit, the function was simplified in successive steps first by removing all time-variability, then by switching to a double-normal function, and finally by switching to a logistic function. The logistic function (for both the fishery and the survey) gave a reasonable fit to the fishery size composition data, the survey size composition data, and the survey age composition data, so it was retained as the final functional form.
3. In general, a "strange" selectivity pattern was defined here as one which was non-monotonic (i.e., where the signs of adjacent first differences changed), particularly if the first differences associated with sign changes were large (in absolute value), and particularly if sign changes in first differences occurred at relatively early ages. Specifically, an index of "strangeness" was defined as follows:
A. Age-specific weighting factors $P_{a}$ were calculated as the equilibrium unfished numbers at age expressed as a proportion of equilibrium unfished numbers.
B. For each year, age-specific first differences in selectivity $\Delta_{a, y}$ were calculated.
C. "Strangeness" was then calculated as:

$$
\left(\frac{1}{y \max -y \min +1}\right) \cdot \sum_{y=y \min }^{y \max } \sqrt{\sum_{a=2}^{a \max }\left(P_{a} \cdot\left(\left(\operatorname{sign}\left(\Delta_{a, y}\right) \neq \operatorname{sign}\left(\Delta_{a-1, y}\right)\right) \cdot\left(\Delta_{a}\right)^{2}\right)\right)}
$$

where the expression $\operatorname{sign}\left(\Delta_{a, y}\right) \neq \operatorname{sign}\left(\Delta_{a-1, y}\right)$ returned a value of 1 if the sign of $\Delta_{a, y}$ differed from the sign of $\Delta_{a-1, y}$ and a value of 0 otherwise. This index attains a minimum of 0 when selectivity is constant across age (or varies monotonically) and a maximum of 1 if selectivity alternates between values of 0 and 1 at all pairs of adjacent ages.
A time series of selectivity at age (for a given fleet) was determined to be "strange" if the index described above exceeded a value of 0.05 . If a model produced a "strange" selectivity pattern, the standard deviations of the prior distributions for the selectivity parameters and the standard deviations of any selectivity dev vectors were decreased proportionally relative to the values estimated for Model 15.6 in last year's assessment until the threshold value of 0.05 was satisfied.

As in previous assessments, development of the final versions of all models included calculation of the Hessian matrix and a requirement that all models pass a "jitter" test of 50 runs. In the event that a jitter run produced a better value for the objective function than the base run, then:

1. The model was re-run starting from the final parameter file from the best jitter run.
2. The resulting new control file, with the parameter estimates from the best jitter run incorporated as starting values, became the new base run.
3. The entire process (starting with a new set of jitter runs) was repeated until no jitter run produced a better value for the objective function than the most recent base run.

One difference from previous assessments is that, for this preliminary assessment, an attempt was made to standardize the bounds within which individual parameters were "jittered." Specifically, once a model was ready to be subjected to the jitter test, the bounds for each parameter in the model were adjusted to match the $99.9 \%$ confidence interval (based on the normal approximation obtained by inverting the Hessian matrix). A jitter rate (equal to half the standard deviation of the logit-scale distribution from which "jittered" parameter values are drawn) was set at 1.0 for all models. Standardizing the jittering process in this manner may not explore parameter space as thoroughly as in previous assessments; however, it should make the jitter rate more interpretable, and show the extent to which the identified minimum (local or otherwise) is well behaved.

Except for selectivity parameters and annual catchability deviations (trawl survey only) in Models 16.216.5 and dev vectors in all models, all parameters were estimated with uniform prior distributions.

All selectivity devs were assumed to be additive (SS automatically assumes log recruitment devs to be additive).

Parameters estimated outside the assessment model (e.g., weight-at-length parameters, maturity-at-age parameters, ageing error matrix, trawl survey catchability in Model 11.5) were likewise described in last year's final assessment (Thompson 2015), and were not re-estimated for this preliminary assessment.

## Model 11.5: main features

Some of the main features characterizing Model 11.5 are as follow:

1. Age- and time-invariant natural mortality, estimated outside the model
2. Parameters governing time-invariant mean length at age estimated internally
3. Parameters governing width of length-at-age distribution (for a given mean) estimated internally
4. Ageing bias parameters estimated internally
5. Gear-and-season-specific catch and selectivity for the fisheries
6. Double normal selectivity for the fisheries and survey, with parameterization as follows:

P1. beginning_of_peak_region (where the curve first reaches a value of 1.0)
P2. width_of_peak_region (where the curve first departs from a value of 1.0)
P3. ascending_width (equal to twice the variance of the underlying normal distribution)
P4. descending_width (equal to twice the variance of the underlying normal distribution)
P5. initial_selectivity (at minimum length/age)
P6. final_selectivity (at maximum length/age)
All parameters except beginning_of_peak_region are transformed: The ascending_width and descending_width are log-transformed and the other three parameters are logit-transformed.
7. Length-based selectivity for the fisheries
8. Age-based selectivity for the survey
9. Fishery selectivity estimated for "blocks" of years
10. Survey selectivity constant over time, except with annual devs for the ascending_width parameter
11. Survey size composition data used in all years, including those years with age composition data (at the request of Plan Team members, inclusion of survey size composition data in all years was instituted in the 2011 assessment and has been retained ever since, based on the view that the costs of double-counting are outweighed by the benefits of including this information for estimation of growth parameters)
12. Fishery CPUE data included but not used for estimation
13. Mean size at age included but not used for estimation

## Model 11.5: iterative tuning

## Iterative tuning of time-varying parameters

The standard deviations of the two dev vectors in Model 11.5 (the log of age 0 recruitment and the survey ascending_width parameter, both additive) were estimated iteratively during the 2009 assessment by tuning the specified $\sigma$ term for each vector to the standard deviation of the elements in that vector. Although this method is more justifiable than simply guessing at the value of $\sigma$, it is known to be biased low, and in the worst case may return a value of zero even when the true value is substantially greater than zero (Maunder and Deriso 2003, Thompson in prep.).

Per request of the BSAI Plan Team, the values of these $\sigma$ terms ( 0.57 and 0.07 , respectively) have been held constant in Model 11.5 and its predecessors ever since the 2009 assessment.

## Iterative tuning of survey catchability

Survey catchability was estimated iteratively during the 2009 assessment by tuning $Q$ so that the average of the product of $Q$ and survey selectivity across the $60-81 \mathrm{~cm}$ size range matched the point estimate of 0.47 given by Nichol et al. (2007).

Per request of the BSAI Plan Team, this value of $Q(0.77)$ has been held constant in Model 11.5 and its predecessors ever since the 2009 assessment.

## Model 15.6: main features

Note that Model 15.6 was not among the models requested by the JTS and SSC for this preliminary assessment. However, it provides the starting point for Models 16.1-16.5, so it is appropriate to review its features.

Except for procedures related to iterative tuning (see next section), the main differences between Model 15.6 and Model 11.5 were as follow:

1. Each year consisted of a single season instead of five.
2. A single fishery was defined instead of nine season-and-gear-specific fisheries.
3. Composition data were given a weight of unity if the harmonic mean of the effective sample size was greater than the mean input sample size of 300 ; otherwise, composition data were weighted by tuning the mean input sample size to the harmonic mean of the effective sample size.
4. The survey was assumed to sample age 1 fish at true age 1.5 instead of 1.41667 .
5. Initial abundances were estimated for the first 20 age groups instead of the first three.
6. The natural mortality rate was estimated internally.
7. The SS feature known as "Fballpark" was turned off (this feature, which functions something like a very weak prior distribution on the fishing mortality rate in some specified year, did not appear
to be providing any benefit in terms of model performance, and what little impact it had on resulting estimates was not easily justified).
8. The base value of survey catchability was estimated internally.
9. Survey catchability was allowed to vary annually.
10. Selectivity for both the fishery and the survey were allowed to vary annually.
11. Selectivity for both the fishery and survey was modeled using a random walk with respect to age (SS selectivity-at-age pattern \#17) instead of the usual double normal.
12. Selectivity at ages $9+$ was constrained to equal selectivity at age 8 for both the fishery and the survey.

## Model 15.6: iterative tuning

Note that the iterative tuning described in this section pertains to the development of Model 15.6 in last year's preliminary assessment. The values resulting from last year's tuning were, with a very few exceptions, retained for Models 16.1-16.5.

All iterative tuning procedures described below were undertaken simultaneously.

## Iterative tuning of prior distributions for selectivity parameters

Initially, the model was run with recruitment as the only time-varying quantity, with the standard deviation of log-scale recruitment estimated internally (i.e., as a free parameter), and with large standard deviations in the prior distributions for all selectivity parameters.

Once the initial model converged, a pair of transformed logistic curves was fit to the point estimates of the fishery and survey selectivity schedules (a transformed logistic curve was used because the selectivity parameters in pattern \#17 consist of the backward first differences of selectivity on the log scale, rather than selectivity itself; Thompson and Palsson 2013). The respective transformed logistic curve (fishery or survey) was then used to specify a new set of means for the selectivity prior distributions (one for each age). A constant (across age) prior standard deviation was then computed such that no age had a prior CV (on the selectivity scale, not the transformed scale) less than $50 \%$, and at least one age had a prior CV of exactly $50 \%$.

The model was then run with the new set of prior means and constant prior standard deviations (one for the fishery, one for the survey), then a new pair of transformed logistic curves was fit to the results, and the process was repeated until convergence was achieved.

## Iterative tuning of time-varying catchability

Although conceptually similar to a dev vector, SS treats each annual deviation in $\ln (\mathrm{Q})$ as a true parameter, with its own prior distribution. Because SS works in terms of $\ln (Q)$ rather than $Q$, normal prior distributions were assumed for all annual deviations. To be parsimonious, a single $\sigma$ was assumed for all such prior distributions.

Unlike the size composition or age composition data sets, the time series of survey abundance data includes not only a series of expected values, but a corresponding series of standard errors as well. This fact formed the basis for the iterative tuning of the $\sigma$ term for time-varying $Q$ in Model 15.6. The procedure involved iteratively adjusting $\sigma$ until the root-mean-squared-standardized-residual for survey abundance equaled unity.

## Iterative tuning of time-varying parameters other than catchability

The following algorithm was used in Model 15.6 (Thompson in prep.; note that this is a multivariate generalization of one of the methods mentioned by Methot and Taylor (2011, viz., the third method listed on p. 1749)):

1. Set initial guesses for the os.
2. Run SS.
3. Compute the covariance matrix (V1) of the set of $d e v$ vectors (e.g., element $\{i, j\}$ is equal to the covariance between the subsets of the ith dev vector and the $j$ th dev vector consisting of years that those two vectors have in common).
4. Compute the covariance matrix of the parameters (the negative inverse of the Hessian matrix).
5. Extract the part of the covariance matrix of the parameters corresponding to the dev vectors, using only those years common to all dev vectors.
6. Average the values in the matrix obtained in step 5 across years to obtain an "average" covariance matrix (V2).
7. Compute the vector of os corresponding to $\mathbf{V} 1+\mathbf{V} 2$.
8. Return to step 2 and repeat until the os converge.

To speed the above algorithm, the os obtained in step 7 were sometimes substituted with values obtained by extrapolation or interpolation based on previous runs.

Unfortunately, given the way that selectivity pattern \#17 is implemented in SS, large gradients can result, particularly if sufficiently large devs occur at or adjacent to the age of peak selectivity. In the event that a large gradient appeared to be unavoidable during the tuning process, selectivity dev vectors were eliminated, one at a time (usually starting at the oldest ages and working downward), until the large gradients disappeared.

## Results

## Overview

The following table summarizes the status of the stock as estimated by the six models ("Value" is the point estimate, "SD" is the standard deviation of the point estimate, "CV" is the ratio of SD to the point estimate, "FSB 2016" is female spawning biomass in 2016 (t), and "Bratio 2016" is the ratio of FSB 2016 to $B_{100 \%}$; color shading for FSB 2016 and Bratio 2016 extends from red (low) to green (high) for each quantity):

|  | Model 11.5 |  | Model 16.1 |  |  | Model 16.2 |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Quantity | Value | SD | CV | Value | SD | CV | Value | SD |
| CV |  |  |  |  |  |  |  |  |
| FSB 2016 | 457,341 | 30,739 | 0.07 | 414,941 | 40,176 | 0.10 | 399,149 | 67,976 |
| Bratio 2016 | 0.61 | 0.03 | 0.06 | 0.57 | 0.06 | 0.10 | 0.46 | 0.07 |

|  | Model 16.3 |  |  | Model 16.4 |  |  | Model 16.5 |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | :---: |
| Quantity | Value | SD | CV | Value | SD | CV | Value | SD |  |
| CV |  |  |  |  |  |  |  |  |  |
| FSB 2016 | 196,753 | 25,016 | 0.13 | 154,877 | 15,482 | 0.10 | 133,142 | 12,167 |  |
| Bratio 2016 | 0.21 | 0.03 | 0.14 | 0.14 | 0.02 | 0.12 | 0.09 | 0.01 |  |

The six models span wide ranges for these quantities. Estimates of FSB 2016 range from 133,000 t (Model 16.5) to 457,000 t (Model 11.5), and estimates of Bratio 2016 range from 0.09 (Model 16.5) to 0.61 (Model Model 11.5). The quantities FSB 2016 and Bratio 2016 tend to covary directly in these models.

## Goodness of fit

Objective function values and parameter counts are shown for each model in Table 2.1.4a, and multipliers used to adjust multinomial sample sizes are shown in Table 2.1.4b. Objective function values are not directly comparable across models, because different data files are used for some models, different constraints are imposed, and the number and types of parameters vary considerably.

Figure 2.1.1a shows the fits of all six models to the trawl survey abundance data; Figure 2.1.1b shows the fits of Models 16.2, 16.4, and 16.5 to the IPHC longline survey abundance data; and Figure 2.1.1c shows the fits of Models 16.3, 16.4, and 16.5 to the NMFS longline survey abundance data.

Table 2.1.5 shows goodness of fit for the survey abundance data. Four measures are shown: root mean squared error (for comparison, the average log-scale standard error "oave" is also shown), mean normalized residual, standard deviation of normalized residuals, and correlation (observed:estimated). For the trawl survey data, Models 16.2-16.5 all give root mean squared errors close to oave. Models 16.1-16.5 all give mean normalized residuals close to zero, standard deviation of normalized residuals close to unity, and correlations greater close to 0.90 or better. The three models that use the IPHC longline survey data all give mean normalized residuals close to zero and standard deviation of normalized residuals close to unity (note that these models inflate the input $\sigma$ values by an internally estimated amount, and the resulting estimates of oave are fairly high, in the 0.42-0.46 range). However, as with previous attempts to use the IPHC longline survey data, all three of these models give negative correlations. The three models that use the NMFS longline survey data all fit those data fairly well, although the mean normalized residuals from all three of these models is substantially negative, ranging from -0.14 to -0.22 (note that, although these models were all given the opportunity to inflate the input $\sigma$ values by an internally estimated amount, Model 16.3 estimated this additional amount at a very small value ( 0.01 ), and the estimates from Models 16.4 and 16.5 tended to become pinned at the lower bound of zero, so estimation of this additional $\sigma$ was ultimately turned off in the latter two models).

Sample size ratios for the size composition data are shown in Table 2.1.6 (note that input sample sizes are the same for all models except Model 16.5). These results can be summarized as follows:

- Measured as the ratio of the arithmetic mean effective sample size to the arithmetic mean input, the models give values well in excess of unity for all components.
- Measured as the ratio of the harmonic mean effective sample size to the arithmetic mean input sample size, all models give noticeably smaller values, but still in excess of unity in most cases. Exceptions consist of the Aug-Dec longline fishery in Model 11.5, and all components in Model 16.5 , which was tuned explicitly so as to set these ratios equal to unity.

Sample size ratios for the survey age composition data are shown in Table 2.1.7a (all models) and for the fishery age composition data in Table 2.1.7b (Models 16.4 and 16.5 only). Note that input sample sizes for the survey data differ for several models: For Models 11.5 and 16.1, input sample sizes were scaled to the conventional mean of 300 ; for Models 16.2-16.4, input sample sizes were left at the values tuned in last year's assessment for Model 15.6 so that $\mathrm{H}(\mathrm{Neff}) / \mathrm{A}(\mathrm{Ninp})=$; and for Model 16.5, arithmetic mean input sample sizes were tuned in this year's assessment so that $\mathrm{H}(\mathrm{Neff}) / \mathrm{A}(\mathrm{Ninp})=1$. The input sample sizes for the fishery data also differ between the two models that use those data: For Model 16.4, mean input sample sizes were assumed equal to mean input sample size for the survey agecomp data; while for

Model 16.5, input sample sizes were tuned in this year's assessment so that $\mathrm{H}(\mathrm{Neff}) / \mathrm{A}(\mathrm{Ninp})=1$. The results can be summarized as follows:

- Measured as the ratio of the arithmetic means, Models 16.2-16.5 give values greater than unity for the survey age composition data (Models 11.5 and 16.1 do not), and Model 16.5 is the only one of the two models using fishery age composition data to achieve a value greater than unity.
- Measured as the ratio of the harmonic mean effective sample size to the arithmetic mean input sample size, Model 16.5 gives values essentially equal to unity for both the survey and fishery age composition data (as this was the tuning criterion for that model), while the other models all give values much less than unity. Note that Punt (in press) concluded that the harmonic mean was a much more appropriate numerator than the arithmetic mean.

Figure 2.1.2 shows the fits to the survey age composition data (all models), and Figure 2.1.3 shows the fits to the fishery age composition data (Models 16.4 and 16.5 only).

## Parameter estimates, time series, and retrospective analysis

Table 2.1.8 lists key parameters estimated internally in at least one of the models, along with their standard deviations.

In Model 16.5, the natural mortality rate $M$ varies as a function of age, following the approach described by Lorenzen $(1996,2011)$. The entry for this model in Table 2.1.8 corresponds to the value at the age at $50 \%$ maturity (rounded to the nearest integer, 5 ). The full schedule of $M$ values for Model 16.5 is shown below:

| Age: | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| M: | 1.022 | 0.548 | 0.337 | 0.259 | 0.218 | 0.194 | 0.178 | 0.167 | 0.159 | 0.153 | 0.149 |
| Age: |  | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 |
| M: |  | 0.146 | 0.143 | 0.141 | 0.140 | 0.139 | 0.138 | 0.137 | 0.136 | 0.136 | 0.135 |

The estimates of log catchability for the trawl survey shown in Table 2.1.8 map into the following estimates of catchability on the natural scale, spanning the range 0.643 (Model 16.1) to 1.590 (Model 16.5):

| Model 11.5 |  | Model 16.1 |  | Model 16.2 |  | Model 16.3 |  | Model 16.4 |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Model 16.5 |  |  |  |  |  |  |  |  |  |
| Est. | SD | Est. | SD | Est. | SD | Est. | SD | Est. | SD |
| 0.770 | $\mathrm{n} / \mathrm{a}$ | 0.643 | 0.063 | 1.050 | 0.108 | 1.581 | 0.075 | 1.343 | 0.065 |

Selectivity schedules are plotted for the fishery in Figure 2.1.4, the trawl survey in Figure 2.1.5a, the IPHC longline survey in Figure 2.1.5b, and the NMFS longline survey in Figure 2.1.5c. All models estimate strongly domed trawl survey selectivity schedules, which is difficult to reconcile with the results of field experiments summarized by Weinberg et al. (2016).

Time series estimated by the models are shown for total biomass, female spawning biomass relative to $B_{100 \%}$, age 0 recruitment, and fishing mortality relative to $F_{40 \%}$ in Figures 2.1.6, 2.1.7, 2.1.8, and 2.1.9, respectively.

Figure 2.1.10 shows 10 -year retrospectives of spawning biomass for each of the models. Mohn’s $\rho$ (revised) values for the models are shown below:

| Model 11.5 | Model 16.1 | Model 16.2 | Model 16.3 | Model 16.4 | Model 16.5 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0.475 | 0.108 | 0.122 | -0.069 | 0.047 | 0.130 |

## Acknowledgments

Anne Hollowed and the BSAI Groundfish Plan Team provided reviews of this preliminary assessment. Jim Ianelli calculated the fishery weights at age and the fishery age compositions. IPHC staff collected the IPHC longline survey data, and Cindy Tribuzio computed the relative population numbers. Dana Hanselman provided the NMFS longline survey data.

Table 2.1.7a—Statistics related to effective sample size (Eff. N) for survey age composition data. "In. N" = input sample size, Mean = arithmetic mean, Harm. = harmonic mean, Ratio1 = arithmetic mean effective sample size divided by arithmetic mean input sample size, Ratio2 = harmonic mean effective sample size divided by arithmetic mean input sample size. For Models 16.2-16.4, arithmetic mean input sample sizes were left at the values tuned in last year's assessment for Model 15.6 so that H(Neff)/A(Ninp)=1 (tan shading). For Model 16.5, arithmetic mean input sample sizes were tuned in this year's assessment so that $\mathrm{H}(\mathrm{Neff}) / \mathrm{A}(\mathrm{Ninp})=1$ (green shading).

Trawl survey age compositions

Table 2.1.7b—Statistics related to effective sample size (Eff. N) for fishery age composition data. "In. N" = input sample size, Mean = arithmetic mean, Harm. = harmonic mean, Ratio1 = arithmetic mean effective sample size divided by arithmetic mean input sample size, Ratio2 = harmonic mean effective sample size divided by arithmetic mean input sample size. For Model 16.4, arithmetic mean input sample size for the fishery agecomp data was assumed equal to arithmetic mean input sample size for the survey agecomp data (purple shading). For Model 16.5, arithmetic mean input sample sizes were tuned in this year's assessment so that $\mathrm{H}(\mathrm{Neff}) / \mathrm{A}(\mathrm{Ninp})=1$ (green shading).

Fishery age compositions

| Year |  |  |  |  | Model 16.4 |  | Model 16.5 |  |
| :---: | :---: | :--- | :--- | :--- | :--- | :---: | :---: | :---: |
