## Preliminary assessment of Pacific cod in the Eastern Bering Sea

Grant Thompson and Jim Thorson

September 17, 2019

## Team and SSC comments

## Comments on assessments in general (1 of 2)

- SSC1: "The SSC requests that all authors fill out the risk table in 2019, and that the PTs provide comment on the author's results in any cases where a reduction to the ABC may be warranted (concern levels 2-4)." Response: This request will be addressed in the final assessment.
- SSC2: "In response to the PT's request for guidance on model averaging and the development of ensembles, the SSC offers the following general recommendations:
- "Progress on this effort will require an example to work through both expected and unanticipated details of how this process may work. The SSC requests again for 2019 that one or more assessments bring forward an ensemble of models.
- "The combining of model output should occur on the basic estimates from the assessment (biomass, F, etc.) and not the reference points themselves.
- (continued on next slide)

## Comments on assessments in general (2 of 2)

- SSC2, continued:
- "Where variance estimates among models differ appreciably, it may be more appropriate to combine the posterior distribution functions from each model than to average the expectations.
- "It will be difficult for the PTs to combine model results without the author's assistance. Such an approach should only be attempted in unique cases, and it is preferable for the author to identify the intention to bring forward an ensemble in September and perform the analysis before the November PT meetings."
- Response: A new method for model weighting that may be useful in developing an example will be the subject of the next presentation. Although it does not satisfy the recommendation to operate on the "basic estimates from the assessment (biomass, F, etc.)," it does satisfy the recommendation to average posterior distribution functions.

## Comments specific to this assessment (1 of 14)

- "For next year's assessment, the Team recommended that...
- BPT1: "...the EBS Pacific cod ages be examined for potential biases and reader effects as seen with GOA Pacific cod (i.e., Barbeaux et al 2018/GOA cod assessment and Kastelle et al., 2017/Age validation of Pacific cod (Gadus macrocephalus) using high-resolution stable oxygen isotope ( $\delta 180$ ) chronologies in otoliths)." Response: All assessments of the EBS Pacific cod stock since 2009 have included estimates of ageing bias, and this practice is continued in all models presented here. In response to a recent concern that ageing criteria may have shifted after 2007, three of the models presented here include separate estimates of ageing bias for the pre-2008 and post2007 portions of the time series.

## Comments specific to this assessment (2 of 14)

- BPT2: "...fisheries data be examined to determine if there are withinyear patterns that may indicate seasonal movement, and if the survey timing may intersect with that seasonal migration." Response: The requested analysis is presented in the Discussion section.
- BPT3: "...a model-based survey time-series be developed that can predict combined abundance of the expanded EBS survey area and the Northern Bering Sea survey area for all years. Length and age compositions should also be created that account for and are appropriately weighted by these model-based estimates. Validate the predictions using various methods as well as consistency with observations from other external surveys (e.g., BASIS)."
- (response on next slide)

## Comments specific to this assessment (3 of 14)

- Response to BPT3: A model-based survey time series for the combined EBS and Northern Bering Sea (NBS) areas, based on the vector autoregressive spatio-temporal (VAST) method developed by Thorson (2019), has been developed and is used in two of the models presented here, as are corresponding VAST estimates of survey age composition. However, when attempts were made to estimate corresponding VAST estimates of survey size composition, the $1-\mathrm{cm}$ bin size currently used in the models caused computational problems that have not yet been resolved. Validation of the estimates "using various methods and comparison for consistency with other surveys" has not been attempted.
- BPT4: "...the NBS survey be conducted again in 2019 to provide data for the Pacific cod assessment." Reponse: The NBS survey was conducted again in 2019 and will provide data for the Pacific cod assessment.

## Comments specific to this assessment (4 of 14)

- BPT5: "...Pacific cod fishery catches and Pacific cod survey data in Russia be researched and summarized." Response: A small amount of data on Russian catches of Pacific cod has been obtained and efforts to obtain further estimates, perhaps using Automatic Identification System data, are being discussed. The available data will be reported in the final assessment.
- BPT6: "...the significance of retrospective patterns when using a time-series with data mainly in recent years (for example, removing 2017 and 2018 leaves only one observation for the Northern Bering Sea survey time-series) be investigated and explained. For example, are the Mohn's $\rho$ estimates useful to compare across models?" Response: Some results pertaining to this issue are presented in the Discussion section.

## Comments specific to this assessment (5 of 14)

- BPT7: "...the author considers an ensemble of models using the three hypotheses discussed above to address the structural uncertainty resulting from these hypotheses, as well as additional uncertainties captured by various models. The three hypotheses are 1) P. cod in the NBS are insignificant to the managed stock, 2) P. cod in the NBS are simply the same stock as in the EBS and should be managed as one stock, and 3) P. cod in the NBS and EBS are from the same stock and should be managed as one stock, but P. cod in the NBS should be modeled separately within one model with separate catchability and selectivity to capture differences observed in the fish in that area. Response: In addition to the base model, six new models are presented here, spread across the Team's three hypotheses (specifically, two new models per hypothesis).

## Comments specific to this assessment (6 of 14)

- BPT8: "...the author considers bringing forward an ensemble of models to capture structural uncertainty with a justifiable weighting as well as a "null" approach with equal weights. The Plan Team may also consider an ensemble even if not recommended by the author. If an ensemble is used, all model outputs in the ensemble that are management related should be averaged, and the ABC should be determined from those averaged outputs (i.e., the application of the control rule to averaged biological reference values). The Team would appreciate feedback from the SSC on appropriate methods to average model outputs to determine an ABC." Response: See Comment SSC2. The presentation on a new model averaging approach includes a focus on justifiable model weights.

## Comments specific to this assessment (7 of 14)

- BPT9: "...the authors coordinate with Council staff to augment the fishery information section of the assessment for next year. Council staff will be providing a cod allocation review in 2019 and will work with the author to provide pertinent summary sections over the summer." Response: The requested augmentation will occur in the final assessment.

## Comments specific to this assessment (8 of 14)

- BPT10: "...the authors coordinate with Alaska Department of Fish and Game on assessment data needs from the state managed Area O Pacific cod fishery as the fishery GHL is expanded under new allocation rules from 6.4\% to a maximum 15\% of the Bering Sea Pacific cod ABC." Response: Representatives from the Alaska Department of Fish and Game have been contacted regarding the need for data from the State-managed Pacific cod fishery in the EBS. They indicate a willingness to begin collecting these data. Specifics of the collection process will be developed soon.

## Comments specific to this assessment (9 of 14)

- SSC3: "The SSC recommends that future efforts focus on treatment of the Northern Bering Sea data prior to adding to the assessment - via summation of the components (as in model 16.6i) or through modelbased approaches that can estimate contributions of unsampled areas (such as developed for EBS walleye pollock). However, the SSC noted that many requested changes made in development of the 17.x and 18.x series of models represent improvements over the 16.x models. These improvements include inclusion of fishery age composition data, the prior on natural mortality, composition data weighted by the number of hauls, and harmonic mean composition weights. Other changes continue to be worthy of evaluation, but may not be clear improvements, such as time-varying selectivity and catchability. The SSC recommends bringing these branched model series back together either in the form of one model, or an ensemble of models for 2019."
- (Response on next slide)

## Comments specific to this assessment (10 of 14)

- Response to SSC3: Results from Model 16.6i, which uses simple summation of the design-based survey estimates, are again reported here, along with results from six new models, two of which use VAST estimates of survey abundance and age composition (see Comment BPT3). All of the new models include fishery age composition data and initial weighting of compositional data by the number of hauls (in either absolute or relative terms), and three of the new models include reweighting of compositional data and time-varying selectivity and catchability.
- SSC4: "The greatest concern identified by the SSC was the future survival and contribution to the greater cod stock of the fish observed in the Northern Bering Sea (over half of the total biomass) in 2018. The SSC reiterated its recommendation from October that in-season reporting of fishery performance be used to track the presence and/or success of these fish into next spring." Response: This request could not be accommodated due to lack of the necessary data.

## Comments specific to this assessment (11 of 14)

- "The SSC agreed with PT recommendations for additional work on...
- SSC5: "...resolving issues with ageing methods and historical age data, following the issues raised in the GOA Pacific cod assessment which may be applicable in the Bering Sea." Response: See Comment BPT1.
- SSC6: "...use of a model-based method for developing a survey abundance estimate for the entire Bering Sea." See Comment BPT3.
- SSC7: "...the critical importance of a Northern Bering Sea survey in 2019." See Comment BPT4.

## Comments specific to this assessment (12 of 14)

- SSC8: "The SSC strongly supported the PT approach of organizing alternative models around explicit hypotheses regarding the assessment structure or population dynamics. This approach was very helpful to make clear where the need for additional research was most important, and also provided a logical framework for developing an ensemble of models corresponding to each hypothesis. Moving forward, weighting of models for an ensemble may be developed based on the relative plausibility of each model hypothesis. The SSC recommends further efforts in developing this approach." Response: See Comment BPT7 regarding the Team's three hypotheses. See Comments SSC2 and BPT8 regarding model averaging. In addition to including a focus on justifiable model weights, the document describing a new model averaging approach also provides an explicit role for the relative plausibility of each model in the ensemble.

## Comments specific to this assessment (13 of 14)

- SSC9: "The SSC supports tagging, which may be helpful for understanding connectivity among areas of the greater Bering Sea." Response: This year's NBS survey included plans to fit 32 fish with satellite archival tags. Genetic samples were to be taken prior to release, to determine spawning site fidelity.
- SSC10: "The SSC supported the use of projections integrated with the assessment analysis and the use of fixed catches (rather than fishing mortality rates) in these projections. This approach provided for more realistic projections that included uncertainty in the fishing mortality rate, parameter uncertainty, and allowed for the explicit calculation of the probability of exceeding the overfishing limit. The SSC suggest that this method be explored in other assessments and considered for routine use." Response: Projections are again integrated with the assessment analysis here.

## Comments specific to this assessment (14 of 14)

- SSC11: "The SSC also encouraged additional work to investigate recent and historical fishery catch in the Northern Bering Sea as there were a number questions regarding reports of fishery activity, but only a small amount of fishing identified by the author." Response: Additional investigation revealed that the absence of fishery data from the NBS survey area last year was due to the timing of last year's analysis. Last year's data query was run in July, and resulted in very few records. However, when the same query was run this July, 620 records (hauls) were retrieved for 2018, all but 12 of which were for the months August-December. No records were retrieved for 2019 as a result of this year's query, however.

## Models

## Base model

- Model 16.6 i was adopted by the SSC last year as the new base model.
- Its main structural features are as follow:
- One fishery, one gear type, one season per year.
- Logistic age-based selectivity for both the fishery and survey.
- External estimation of time-varying weight-at-length parameters and the standard deviations of ageing error at ages 1 and 20.
- All parameters constant over time except for recruitment and $F$.
- Internal estimation of all natural mortality, fishing mortality, length-at-age (including ageing bias), recruitment (conditional on Beverton-Holt recruitment steepness fixed at 1.0), catchability, and selectivity parameters.
- The only difference between Model 16.6 i and Model 16.6 is the inclusion in Model 16.6 of data from the NBS survey, which were incorporated by simple summation with the EBS survey data.

## Alternative models (1 of 6)

- A total of six alternative models are presented here in addition to the base model.
- These constitute a factorial design involving the Team's three hypotheses regarding treatment of the NBS (Comments BPT7 and SSC8) and the SSC's desire to explore multiple ranges of possible enhancements to the structure of the base model (Comment SSC3).
- Reprising the Team's three hypotheses:

1. Pacific cod in the NBS are insignificant to the managed stock, so the assessment should include data from the EBS only.
2. Pacific cod in the EBS and NBS comprise a single stock, and the EBS and NBS surveys can be modeled in combination.
3. Pacific cod in the EBS and NBS comprise a single stock, but the EBS and NBS surveys should be modeled separately.

## Alternative models (2 of 6)

- Relative to the base model, two ranges of structural modifications are featured among the alternative models.
- More specifically, two models are presented for each hypothesis, one of which contains a certain set of structural modifications, and the other of which contains a second, larger, set of structural modifications.
- The two sets of structural modifications are the same across hypotheses, except that an additional set of survey parameters is required for Hypothesis 3.
- In addition to structural differences, the models for the various hypotheses also involve different data.

## Alternative models (3 of 6)

- The first (smaller) set of structural modifications is as follows:
- Set input sample size for compositional data equal to the number of hauls, rescaled to an average of 300 for each component (Model 16.6i sets input sample size equal to the number of observations, rescaled to an average of 300 for each component).
- Include the available fishery age composition data (Model 16.6i ignores those data).
- Use age-based, double-normal selectivity, potentially domeshaped for the fishery but forced asymptotic for the survey (Model 16.6i uses age-based, logistic selectivity for both fleets).
- Tune the input standard deviation of log-scale recruitment deviations $\left(\sigma_{R}\right)$ to match the square root of the variance of the estimates plus the sum of the estimates' variances (Methot and Taylor 2011; Model 16.6i estimates $\sigma_{R}$ internally).
- Use size-based maturity (Model 16.6i uses age-based maturity).

## Alternative models (4 of 6)

- The second (larger) set of structural modifications is as follows:
- Set input sample size for compositional data equal to raw number of hauls rather (than rescaled to an average of 300).
- Reweight compositional data internally using the Dirichlet-multinomial distribution (Thorson et al. 2017; see also Discussion).
- Use size-based double-normal selectivity rather than age-based (but keeping the assumption of asymptotic survey selectivity).
- Allow mean ageing bias at ages 1 and 20 to differ between the pre2008 and post-2007 periods in order to compensate for an apparent change in ageing criteria (Beth Matta, AFSC, pers. comm., 6/27/19) .
- Allow yearly variation in survey selectivity (two parameters), with the input standard deviation of the deviations tuned to set the variance of the estimates plus the sum of the estimates' variances equal to unity.
- (continued on next slide)

## Alternative models (5 of 6)

- The second (larger) set of structural modifications (continued):
- Allow yearly random variation in survey catchability, with the input standard deviation of the deviations tuned to set the variance of the estimates plus the sum of the estimates' variances equal to unity.
- Allow yearly random variation in mean length at age 1.5 , with the input standard deviation of the deviations tuned to set the variance of the estimates plus the sum of the estimates' variances equal to unity, in order to address the significant amount of time-variability in growth documented by Puerta et al. (2019).
- Allow yearly random variation in fishery selectivity (three parameters), with the input standard deviation of the deviations tuned to set the variance of the estimates plus the sum of the estimates' variances equal to unity.

## Alternative models (6 of 6)

- Referring to models conforming to the first set of structural modifications as "simple" and models conforming to the second (larger) set of structural modifications as "complex," the set of alternative models can be summarized as follows:

| Hypothesis: | 1: EBS only |  | 2: Combine EBS and NBS |  | 3: Separate EBS and NBS |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Structure: | Simple | Complex | Simple | Complex | Simple | Complex |
| Name: | M19.1 | M19.2 | M19.3 | M19.4 | M19.5 | M19.6 |

## Features explored but not included

- Use of VAST survey index estimates without the cold pool covariate.
- Use of VAST estimates of survey abundance without bias correction.
- Internal estimation of a time-invariant "extra" survey standard error.
- Allowing yearly random variation in the Brody growth coefficient $(K)$.
- Internal estimation of a parameter expressing cohort-specific growth.
- External re-weighting of compositional data components.
- Survey catchability fixed (i.e., not estimated statistically) at 1.0.
- Exponential-logistic fishery selectivity.
- Exponential-logistic survey selectivity.
- Different sets of selectivity parameters subject to random variation.
- Allowing survey selectivity to be dome-shaped.

Data

## Input composition sample sizes

- The rescaled number of observations used as input sample sizes in Model 16.6 i were replaced by:
- rescaled number of hauls (Models 19.1, 19.3, 19.5) or
- raw number of hauls (Models 19.2, 19.4, 19.6).

## Abundance indices

- The design-based EBS+NBS survey estimates used in Model 16.6i were replaced by:
- Design-based EBS-only survey estimates in Models 19.1 and 19.2 (Hypothesis 1).
- VAST estimates for the combined surveys in Models 19.3 and 19.4 (Hypothesis 2).
- Bias-corrected, with cold pool covariate.
- Settings followed the recommendations given by Thorson (2019).
- Estimates suggest that few Pacific cod were present in the NBS during years when that region was not surveyed.
- Area-specific design-based estimates for the EBS and NBS surveys in Models 19.5 and 19.6 (Hypothesis 3).

## VAST vs. design-based EBS+NBS index

NOAA FISHERIES
U.S. Department of Commerce | National Oceanic and Atmospheric Administration | NOAA Fisheries | Page 31 This information is distributed solely for the purpose of pre-dissemination peer review under applicable information quality guidelines. It has not been formally disseminated by the National Marine Fisheries Service and should not be construed to represent any agency determination or policy.

## Age composition

- The VAST estimates of age composition were substituted for their design-based counterparts in all models.
- The differences between the two sets of estimates (VAST minus design-based) are shown on the next slide, where the color scale extends from red=low to green=high.
- In general differences between the two sets of estimates are small:
- $84 \%$ of the cells fall within the range $(-0.01,0.01)$,
- $95 \%$ fall within the range $(-0.02,0.02)$, and
- $99 \%$ fall within the range ( $-0.04,0.04$ ).
- Age 1 had the largest positive changes ( $4 \%$ increases in 1997 and 2009, $5 \%$ increase in 2011).
- Ages 2 and 3 had the largest negative changes ( $4 \%$ decreases at age 2 in 2013 and age 3 in 1997).

## VAST vs. design-based survey agecomp

| Year | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |

## Results

## Bridging analysis, part 1 (1 of 4)

- The differences between Model 16.6 i and Model 19.3 serve as a convenient bridge from the base model to the set of alternative models.
- Both have a relatively simple structure and both use data from the combined EBS and NBS surveys.
- The steps can be outlined as follow, where Steps 1-4 all involve changes in data and Steps 5-8 all involve changes in model structure:

| Step | Description |
| :---: | :--- |
| 0 | Model 16.6i (base model) |
| 1 | Same as Step 0, but using VAST survey index |
| 2 | Same as Step 1, but using VAST agecomps |
| 3 | Same as Step 2, but with sizecomp N = rescaled number of hauls |
| 4 | Same as Step 3, but with fishery agecomp data included ( $\mathrm{N}=$ rescaled no. hauls) |
| 5 | Same as Step 4, but with asymptotic double-normal selectivity (fishery and survey) |
| 6 | Same as Step 5, but with potentially domed fishery selectivity |
| 7 | Same as Step 6, but with SD(ln(recruits)) tuned iteratively |
| 8 | Same as Step 7, but with size-based maturity |

## Bridging analysis, part 2 (1 of 4)

- Next, a bridge from the "simple" Model 19.3 to its "complex" counterpart, Model 19.4 can be created.
- The steps can be outlined as follow, where Step 1 involves a change in data and Steps 2-9 all involve changes in model structure:

| Step | Description |
| :---: | :--- |
| 0 | Model 19.3 |
| 1 | Same as Step 0, but with composition input N = number of hauls (no rescaling) |
| 2 | Same as Step 1, but with Dirichlet composition data weights |
| 3 | Same as Step 2, but with size-based selectivity |
| 4 | Same as Step 3, but with block-specific ageing bias (pre-2008, post-2007) |
| 5 | Same as Step 4, but with yearly random variation in survey selectivity (2 parameters) |
| 6 | Same as Step 5, but with re-tuned SD(ln(recruits)) |
| 7 | Same as Step 6, but with yearly random variation in survey catchability |
| 8 | Same as Step 7, but with yearly random variation in mean length at age 1.5 |
| 9 | Same as Step 8, but with yearly random variation in fishery selectivity (3 parameters) |

## Alternative measures of effective sample size

- The Dirichlet-multinomial distribution implies its own measure of effective sample size (Thorson et al. 2017), which can be compared to the traditional measure of effective sample size popularized by McAllister and lanelli (1997)

| Component | Average no. hauls |  |  | Thorson N |  |  | McAllister-Ianelli N |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | M19.2 | M19.4 | M19.6 | M19.2 | M19.4 | M19.6 | M19.2 | M19.4 | M19.6 |
| Fishery sizecomps | 5225 | 5225 | 5225 | 5225 | 5225 | 5225 | 2012 | 2013 | 2007 |
| EBS survey sizecomps | 346 | 352 | 346 | 346 | 352 | 346 | 578 | 561 | 576 |

## Key to figure colors and symbols

- Colors distinguish hypotheses:
- Blue = Models 19.1 and 19.2 (hypothesis 1)
- Orange = Models 19.3 and 19.4 (hypothesis 2)
- Green = Models 19.5 and 19.6 (hypothesis 3 )
- Gray = Model 16.6i (base)
- Symbols distinguish levels of complexity:
- Open circles = simple (Models 19.1, 19.3, and 19.5)
- Solid circles = complex (Models 19.2, 19.4, and 19.6)
- No circles = base (Model 16.6i)

## Fits to survey indices

## Length at age 1.5

## Length at age (Models 16.6i and 19.1-19.2)

## Model 16.6i

- Results of regressions with fishery CPUE as the dependent variable:

| Parameter | 2017 model |  | 2018 model |  | $2017-2018$ model |  |
| :--- | ---: | ---: | ---: | ---: | ---: | :---: |
|  | Est. | Est./SD | Est. | Est./SD | Est. | Est./SD |
| Intercept | $-4.85 \mathrm{E}+05$ | $8.03 \mathrm{E}+00$ | $-4.34 \mathrm{E}+04$ | $6.88 \mathrm{E}-01$ | $-3.53 \mathrm{E}+05$ | $8.74 \mathrm{E}+00$ |
| Day | $2.39 \mathrm{E}+03$ | $8.45 \mathrm{E}+00$ | $3.01 \mathrm{E}+02$ | $9.81 \mathrm{E}-01$ | $1.75 \mathrm{E}+03$ | $9.00 \mathrm{E}+00$ |
| Latitude | $8.32 \mathrm{E}+03$ | $7.98 \mathrm{E}+00$ | $6.63 \mathrm{E}+02$ | $6.17 \mathrm{E}-01$ | $6.08 \mathrm{E}+03$ | $8.83 \mathrm{E}+00$ |
| Longitude | $-2.81 \mathrm{E}+03$ | $7.94 \mathrm{E}+00$ | $-2.46 \mathrm{E}+02$ | $6.68 \mathrm{E}-01$ | $-2.05 \mathrm{E}+03$ | $8.65 \mathrm{E}+00$ |
| Day x latitude | $-4.10 \mathrm{E}+01$ | $8.38 \mathrm{E}+00$ | $-4.71 \mathrm{E}+00$ | $9.01 \mathrm{E}-01$ | $-3.00 \mathrm{E}+01$ | $9.05 \mathrm{E}+00$ |
| Day x longitude | $1.39 \mathrm{E}+01$ | $8.38 \mathrm{E}+00$ | $1.74 \mathrm{E}+00$ | $9.69 \mathrm{E}-01$ | $1.02 \mathrm{E}+01$ | $8.93 \mathrm{E}+00$ |
| Latitude x longitude | $4.81 \mathrm{E}+01$ | $7.90 \mathrm{E}+00$ | $3.71 \mathrm{E}+00$ | $5.91 \mathrm{E}-01$ | $3.52 \mathrm{E}+01$ | $8.73 \mathrm{E}+00$ |
| Day x latitude x longitude | $-2.38 \mathrm{E}-01$ | $8.32 \mathrm{E}+00$ | $-2.72 \mathrm{E}-02$ | $8.89 \mathrm{E}-01$ | $-1.74 \mathrm{E}-01$ | $8.98 \mathrm{E}+00$ |

- None of the models fit the data very well ( $\mathrm{R}^{2}$ for the 2017, 2018 , and 2017-2018 models was $0.20,0.05$, and 0.10 , respectively).
- Coefficients of the 2018 model were estimated very imprecisely, although the coefficients of the other two models were fairly well estimated.
- Regardless, the estimated coefficient for day $\times$ latitude was negative in all three models, suggesting that Pacific cod overall are not migrating northward during the summer months.

## Retrospective estimates of $N B S \ln (Q)$

- Gray rows indicate years with NBS surveys
- No NBS data after $8^{\text {th }}$ peel

|  |  | Model 19.5 |  |  | Model 19.6 |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Peel | Last_yr | Est. | SD | Bias | Est. | SD | Bias |
| 0 | 2018 | -1.686 | $1.17 \mathrm{E}-01$ | $\mathrm{n} / \mathrm{a}$ | -1.564 | $3.52 \mathrm{E}-01$ | $\mathrm{n} / \mathrm{a}$ |
| 1 | 2017 | -2.184 | $1.63 \mathrm{E}-01$ | 0.146 | -2.359 | $4.46 \mathrm{E}-01$ | 0.083 |
| 2 | 2016 | -4.527 | $3.92 \mathrm{E}-01$ | 0.206 | -2.258 | $9.47 \mathrm{E}-01$ | 0.236 |
| 3 | 2015 | -4.604 | $3.83 \mathrm{E}-01$ | 0.428 | -2.359 | $9.41 \mathrm{E}-01$ | 0.345 |
| 4 | 2014 | -4.661 | $3.82 \mathrm{E}-01$ | 0.537 | -2.448 | $9.43 \mathrm{E}-01$ | 0.448 |
| 5 | 2013 | -4.793 | $4.54 \mathrm{E}-01$ | 0.695 | -2.547 | $9.48 \mathrm{E}-01$ | 0.553 |
| 6 | 2012 | -4.948 | $5.79 \mathrm{E}-01$ | 0.875 | -2.777 | $9.45 \mathrm{E}-01$ | 0.775 |
| 7 | 2011 | -5.028 | $5.70 \mathrm{E}-01$ | 0.823 | -2.937 | $9.25 \mathrm{E}-01$ | 0.961 |
| 8 | 2010 | -5.143 | $5.58 \mathrm{E}-01$ | 0.833 | -3.089 | $9.40 \mathrm{E}-01$ | 1.231 |
| 9 | 2009 | -1.684 | $1.25 \mathrm{E}+04$ | 0.596 | -1.478 | $1.21 \mathrm{E}+04$ | 1.811 |
| 10 | 2008 | -1.684 | $1.25 \mathrm{E}+04$ | 0.436 | -1.484 | $1.21 \mathrm{E}+04$ | 0.916 |

## Internal estimation of compositional sample size

- Thorson et al. (2017) list the following as reasons to prefer the Dirichlet-multinomial approach:
- The approach is faster than alternatives based on iteration, as the weighting is done internally by estimation of a single additional parameter.
- Because the single additional parameter is estimated, uncertainty in that estimate is propagated appropriately, unlike iterative approaches that result in a fixed constant.
- The same standard for convergence that is used for all other parameters applies to the weighting, unlike iterative approaches.
- The resulting estimates of effective sample size can never exceed the input sample size, which is a desirable property so long as the input sample size is appropriate.

## AFSC internal review comments

- "It would be informative to include a detailed description of the model(s) that were considered, model diagnostics, and AIC statistics if multiple models were explored ... in the November report...."
- "On page 7 you mention that all models include VAST estimates of age composition. Is this true for models 19.1 and 19.2 (the EBS-only models)? ... If the age composition data for models 19.1 and 19.2 include the combined VAST age composition estimates a statement justifying this inclusion is needed."
- "I was surprised to see that the Mohn's rho statistic was higher ... for the complex models. ... I am wondering if time-varying survey selectivity is having a major impact on the retrospective pattern. ... Would time blocks be more appropriate? ... If there are patterns in the residuals this may indicate some aspect of the growth relationship is misspecified...."
- "Have you used CAAL data in your previous models to evaluate if the growth parameters are less sensitive to model assumptions?"
