

Supplemental Analysis of Management Options for the Area 3A Charter Halibut Fisheries for 2020

A Report to the North Pacific Fishery Management Council

Sarah Webster, Robert Powers
Alaska Department of Fish and Game
January 23, 2020

1. Introduction

The Council's Charter Halibut Management Committee met October 29, 2019, to develop alternative management measures to be analyzed by the ADF&G for the 2020 season. Status quo regulations in Regulatory Area 3A include a two fish bag limit: one fish of any size and one less than or equal to 28 inches, a limit of one trip per vessel per day and one trip per charter halibut permit per day, an annual limit of four fish retained while fishing on charter vessels in Regulatory Area 3A, Wednesdays are closed all year, and 5 Tuesdays are closed. The charter committee considered the performance of last year's measures, and in light of recent trends in effort, number of halibut harvested by charter anglers, average weight of halibut, halibut abundance, and economic considerations, identified the following measures in Regulatory Area 3A for analysis for 2020:

- 1) Status quo.
- 2) Fewer or additional Tuesday closures throughout the year.
- 3) Opening all Tuesdays and opening some Wednesdays throughout the year.

Results of ADF&G's analysis of management measures were presented at the December 2019 Council meeting within the context of two possible scenarios based on the IPHC's stock assessment reported at the November 25, 2019 IPHC Interim Meeting (Stewart et al. 2019). The first scenario is consistent with the interim management procedure and uses a coastwide TCEY at the reference level (SPR_{46%}) of 31.9 Mlb; distributed mortality limits use a fixed TCEY for 2A (Washington, Oregon, California); a TCEY for 2B (British Columbia) based on a formula set forth at the 2019 IPHC annual meeting and an additional adjustment to the 2B TCEY for U26 bycatch mitigation; and the Space Time Model proportional distribution for all areas in Alaska. The second scenario uses the status quo TCEY of 38.6 Mlb (equating to an SPR_{40%}) and the same distribution procedures set forth in the previous scenario. None of the management measures requested for Area 3A resulted in removal forecasts that were below either allocation scenario.

Charter Allocation (Mlb) ^a		
Regulatory Area	Reference TCEY	Status Quo TCEY
3A	1.24	1.66

^aThe Reference TCEY uses SPR_{46%} and is 31.9 Mlb. The status quo TCEY (2019) uses SPR_{40%} and is 38.6 Mlb.

Noting that none of the requested analyses resulted in removal estimates within the range of likely allocations, ADF&G staff provided additional analyses to the Charter Halibut Management Committee at their December 3, 2019 meeting. Additional analyses included management measures requested for past analyses. Several options resulted in removal forecasts below the Status Quo TCEY scenario; however, no analyses resulted in removal forecasts at or below the Reference TCEY. As such, the Charter Halibut Management Committee requested, and the Council agreed, to have ADF&G staff analyze a wider range of management measures to include combining day of the week closures and reverse slot limits to make recommendations relative to the Reference TCEY catch allocation specified by the IPHC. The Council intends to review and adopt the Committee's recommended management measures at the February 2020

meeting. Methods and results of additional analyses presented at the Charter Halibut Management Committee in December and ensuing analyses requested by the Committee and the Council are outlined in this document. For information on general methods, analyses presented at the December 2019 Council meeting for Regulatory Area 3A, and analyses for Regulatory Area 2C, see Webster and Powers (2019).

2. Area 3A Management Measures

2.1 Maximum Size Limit on One Fish Combined with Tuesday closures

2.1.1 Approach

Status quo for this regulatory mechanism is a maximum size limit on one fish of 28 inches and five Tuesday closures. Other size limits and Tuesday closures were explored for flexibility in recommending management measures. Charter removals were projected under maximum size limits ranging from 26 to 30 inches and Tuesday closures ranging from zero to thirteen days or for the entire season. Projected removals include a 1.1% inflation factor to account for release mortality. These projections incorporate all other status quo measures.

The analysis followed the same harvest projection procedures as the analysis for Tuesday closures (Webster and Powers 2019).

Average weight under each size limit was calculated as a weighted mean of the fish of any size and the fish subject to a maximum size limit. The average weight for the fish of any size was assumed to be the corrected overall average weight in 2013, the last year without a size limit in Area 3A. The average weight for size-restricted fish was calculated as the corrected average weight of fish less than or equal to the specified size limit in 2013. In recent years, the average weights from 2013 for each size limit differed from average weights observed under those size limits. Factors contributing to those differences include changes since 2013 in the size distribution of the population, changes in the sizes of fish anglers are willing to keep given annual limits, and changes in the proportions of first and second fish in the harvest. Therefore, the predicted average weights were corrected to match current average weights. Corrections were based on the difference between predicted and estimated (observed) average weights for 2017-2019. Average weights for past years tended to be underestimated for all subareas, ranging from 52% below to 7% above observed values across all subareas and years, and from 29% to 16% below observed values across years for Area 3A overall. Correction factors, based on the average ratio of the predicted and observed average weights, ranged from 1.00 to 1.98 among subareas.

These average weights were then weighted by the 2020 projected proportions of harvest made up of “first” and “second” fish in angler’s bag limits. These terms do not refer to the order in which the fish were caught, but rather to whether the fish came from limits of one or two fish. For example, if an angler kept only one halibut on a trip, the fish was designated a “first” fish. If an angler kept two halibut, one was designated “first” and the other “second.” The proportions of “second” fish in the harvest were forecasted for 2020 from 2010-2019 logbook data using the exponentially-weighted time series models described in Webster and Powers (2019). These forecasted proportions ranged from 42-44% in Cook Inlet down to 4-9% in the Glacier Bay and Yakutat subareas, with a weighted average of 36% for Area 3A overall.

2.1.2 Results

Under status quo regulations, which include a 28-inch maximum size limit on the second fish and five Tuesday closures, the projected removal of 1.938 Mlb is approximately 0.70 Mlb more than the Reference TCEY catch allocation of 1.24 Mlb and 0.32 Mlb more than the Status Quo TCEY catch allocation of 1.66 Mlb (Table 1). Closing all Tuesdays and a maximum size of 26 inches on the second fish resulted in a projected removal of 1.696 Mlb, still more than either catch allocation. Specific dates for Tuesday closures can be found in Webster and Powers (2019, Table 22).

2.2 Status Quo with All Tuesdays Closed and Additional Days Closed Combined with Maximum Size Limits

2.2.1 Approach

Status quo regulations in Area 3A included a year-round closure of the charter fishery on Wednesdays, as well as five Tuesdays closed in July and early August. The potential effect of closing all Tuesdays with additional days of the week (Monday or Thursday) closed in June – August was estimated. Other size limits were also explored for flexibility in recommending management measures. Charter removals were projected under maximum size limits ranging from 26 to 30 inches and Monday or Thursday closures ranging from zero to thirteen days or for the entire season. Projected removals include a 1.1% inflation factor to account for release mortality. These projections incorporate all other status quo measures.

The analysis followed the same procedures as the analysis for Tuesday closures (Webster and Powers 2019). The analysis estimated the proportional reduction in halibut harvest with each additional daily closure in 2017 and applied those proportional reductions to the harvest forecast for 2020. 2017 was used as the base year because it is the most recent year with complete data and the same or fewer closed days as status quo.

The first step was to identify the dates of specific days that would be closed in 2020 under each possible number of closed days. Specific days were selected such that, for each scenario, 60-75% of the closed days fall before August 1. Once the specific closed dates for each scenario were identified, the closest date range for the same day of the week was identified from the 2017 data set for analysis. For example, when evaluating closing Mondays from July 16 – August 6, 2020, we used harvest from Mondays between July 13 – August 3, 2017.

The analysis assumed that the proportion of harvest occurring on each date in 2017 would be eliminated if those dates were closed in 2020. The total annual harvest under each scenario of closed days was compared to the harvest scenario of five closed Tuesdays (status quo) to estimate the proportional change for 2020. The harvest reductions under each scenario of closed days represent the maximum expected reduction in the number of fish harvested. A day of the week closure would be unlikely to achieve the maximum reduction in halibut harvest because of the potential for displaced anglers to book alternate dates either on the same vessel or another vessel with available space. There is a substantial amount of latent capacity on charter vessels in Area 3A (Marrinan and Fey 2017).

Methods for changes in the maximum size limit followed the procedures outlined in section 2.1.1.

2.2.2 Results

The potential reductions in harvest relative to status quo ranged from 9.5% for all Tuesdays and no closed Monday or Thursday to 25.1% or 26.3% for all closed Tuesdays and Mondays or Thursdays, respectively (Tables 2 & 4). Proportional reductions and projected removals varied slightly and were generally similar between Monday and Thursday closures. For the entire year, Thursdays had slightly more savings than Mondays. The projected removals were also estimated with a range of maximum size limits of 26 to 30 inches on one fish. Estimated removals associated with these scenarios ranged from 1.781 Mlb for all Tuesdays and one Monday or Thursday closed with a 30-inch size limit on one fish to 1.386 Mlb for all Thursdays closed with a 26-inch size limit (Tables 3 & 5). Many combinations of all Tuesdays closed with additional daily closures and maximum size limits would be possible under the Status Quo TCEY catch allocation of 1.66 Mlb. Additional restrictions would be necessary under the Reference TCEY catch allocation of 1.24 Mlb for 2020.

2.3 Maximum Size Limit on One Fish Combined with Annual Limits of 2 – 4 Fish

2.3.1 Approach

The status quo is a maximum size limit on one fish of 28 inches and an annual limit of four fish. Other size limits and annual limits were explored to provide the Council flexibility in recommending

management measures. Charter removals were projected under maximum size limits ranging from 26 to 30 inches and annual limits of two to four fish. Projected removals include a 1.1% inflation factor to account for release mortality. These projections incorporate all other status quo measures, including the charter vessel trip limit, permit trip limit, Wednesday closure for the entire year, and five Tuesday closures in July and August.

Average weight under each size limit was calculated as described in section 2.1.1.

The effects of various annual limits on harvest were estimated using charter logbook data that summarized the distribution of annual harvests by individual licensed anglers from 2018, the most recent year with complete logbook data. Calculations of annual harvests could not be done for youth anglers because they are not required to be licensed, and therefore harvest cannot be assigned to individuals. Youth accounted for a relatively steady average of 5.4% of charter effort in Area 3A during the years 2016-2018. Because the proportion of youth effort was steady and relatively low, we assume that leaving youth anglers out of the calculations did not bias estimates of the effects of implementing annual limits.

For each subarea, harvests under each proposed annual limit were estimated by truncating the annual harvest of each angler during 2018 at the given annual limit. For example, if 500 anglers harvested four fish each in 2018 (2,000 fish total), then under an annual limit of three fish, that group of 500 anglers would only harvest 1,500 fish. The number of anglers that would be affected by each annual limit was calculated as the number of anglers that harvested more than the given annual limit in 2018. In the example above, all 500 anglers harvested more than three fish and would be affected by a three-fish annual limit, but anglers that harvested three or fewer fish would be unaffected. Using this approach, the annual harvest by licensed anglers was calculated over a range of annual limits and the percentage reduction in harvest was calculated by comparison to their total harvest with an annual limit of four fish (status quo). All calculations were done by subarea and summed to obtain the harvests under each annual limit in Area 3A.

Doing the calculations by subarea slightly underestimates the harvest reductions associated with annual limits because some anglers fish in multiple subareas within a year. For example, if an individual angler caught two fish in each of two subareas in the base year, the analysis by subarea would indicate that a three-fish annual limit would have no effect on that angler's annual harvest in either subarea. In reality, the limit would cut that angler's annual harvest by 25 percent. The degree of underestimation depends on how many anglers fished multiple subareas in a year. The magnitude of this error was evaluated by comparing the percentage harvest reductions estimated from subarea and areawide data. The subarea method underestimated the reductions in harvest by 2.5 to 0.9 percentage points for annual limits from 2 to 4 fish, respectively. The underestimation caused by anglers fishing multiple areas was considered negligible. Furthermore, because this underestimated the reduction of harvest, results are considered conservative estimates.

2.3.2 Results

The effects of annual limits varied by subarea, with the largest effects in the Kodiak, Yakutat, and Cook Inlet subareas (Table 6). Areawide, application of lower annual limits to the harvest would result in harvest reductions of 9.7% under a two-fish annual limit and 3.6% under a three-fish limit. With all other status quo measures in effect, lowering the annual limit from four to three fish is estimated to reduce the harvest from 132,453 to 127,656 halibut and reduce it to 119,660 fish under a two fish annual limit.

An annual limit of two fish and a maximum size limit on one fish of 26-inches resulted in a projected removal of 1.70 Mlb (Table 7). All annual limits and size limits evaluated were insufficient to result in removals that achieved the charter allocation associated with the Reference TCEY or the Status Quo TCEY.

2.4 Maximum Size Limit on One Fish Combined with Annual Limits of 2 – 3 Fish and Tuesday Closures

2.4.1 Approach

The status quo is a maximum size limit on one fish of 28 inches, an annual limit of four fish, and five Tuesday closures. Other combinations of size limits, annual limits, and Tuesday closures were explored to provide the Council flexibility in recommending management measures. Charter removals were projected under maximum size limits ranging from 26 to 30 inches, 1 – 13 Tuesday closures or a Tuesday closure for the entire season and annual limits of two to four fish (see Table 1 for four fish). Projected removals include a 1.1% inflation factor to account for release mortality. These projections incorporate other status quo measures, including the charter vessel trip limit, permit trip limit, and a Wednesday closure for the entire year.

Average weight under each size limit was calculated as described in section 2.1.1. Effects of annual limits were calculated as described in section 2.3.1. These were applied prior to the effect of Tuesday closures as annual limits are expected to have a more definitive effect on harvest. Effects of Tuesday closures were then applied following the methods outlined in Webster and Powers (2019).

2.4.2 Results

Under a three fish annual limit, closing all Tuesdays and a maximum size limit of 26 inches on one fish would be needed for the harvest forecast to be below the Status Quo TCEY catch allocation (Table 8). Under a two fish annual limit, several combinations of size limits and Tuesday closures result in projected removals below the Status Quo TCEY allocation (Table 9). No combinations of maximum size limits, Tuesday closures, and annual limits resulted in projected removals below the Reference TCEY catch allocation.

2.5 Reverse Slot Limit Combined with a Maximum Size Limit

2.5.1 Approach

This measure would combine a reverse slot limit on one fish, as is in place in Area 2C, with the status quo maximum size limit of 28 inches on the second fish. This regulation is functionally similar to a maximum size limit on both fish, but provides anglers with the potential of harvesting one halibut of exceptional size (above the upper limit). All other status quo management measures would remain in place.

Because a reverse slot limit has never been implemented in Area 3A, there were no empirical data on how the fishery might respond to such a regulation. This regulation limits the size of the fish that, under status quo regulations, can be of any length. It was assumed that restricting the length of both fish would increase the incentive to harvest two fish, thereby increasing the HPUE and the number of fish harvested. However, there are no data to indicate how many more second fish would be retained or how much the harvest could increase.

Because a single prediction could not be made with confidence, two scenarios were projected bracketing a plausible range of assumptions. Both scenarios used the 2019 preliminary effort as the projected effort for 2020. The low harvest scenario used the time series forecasts of HPUE and the time series forecast of proportion of second fish for 2020. Use of this scenario assumes that a size limit on both fish would not increase retention of second fish by anglers. The high harvest scenario used the HPUEs and the corresponding proportions of second fish from 2013, the last year before implementation of any size limit. Implementation of the maximum size limit on one fish in 2014 resulted in immediate and substantial decreases in HPUE and the proportion of second fish in subareas with large fish available (Webster and Powers 2019).

The method of projecting removals under this option was a hybrid of the reverse slot and maximum size methods, but still followed the basic logic in Section 2.1. Harvest (numbers of fish) was projected as effort multiplied by HPUE. The average weight of the first fish was projected exactly as was done for the

reverse slot limit in Area 2C (Webster and Powers 2019), but using length data from 2013, the last year without a size limit in Area 3A. The average weight of the second fish was calculated as the average weight of U28 fish in 2013 for the high harvest scenario and the average weight of U28 fish in 2019 for the low harvest scenario. The overall average weight was calculated as a weighted mean of the first and second fish, where the weighting factors were the projected proportions of first and second fish.

Projections were made for lower size limits ranging from 35-60 inches (U35-U60) and upper limits ranging from 60-80 inches (O60-O80). The lack of experience with this measure created another problem, namely there were no empirical mean weight data to correct the predictions to current conditions, as was done with the status quo measures (Webster and Powers 2019). However, imposition of a U60-O60 size limit would be the functional equivalent of one fish of any size and a maximum size limit of 28 inches on the second fish. To correct mean weight, the projections for the low harvest scenario were adjusted by a single correction factor to make the projected yield under a U60-O60 reverse slot limit match the projected yield under the status quo (one fish of any size plus one fish under 28 inches). Correcting the yield was the functional equivalent of correcting mean weight because under the low harvest scenario and the status quo forecast, harvest (number of fish) was the same. This same correction factor was used to correct for mean weight under the high harvest scenario.

Finally, the yield projections were inflated by a factor of 4% to account for release mortality. This is higher than the release mortality inflation factor used for standard projections because there will likely be an increase in number and size of released fish under a reverse slot limit, but lower than the value used for 2C because of differences in observed length distributions between the two Areas. This number was selected arbitrarily, as there were no data upon which to base an estimate. However, we know from reverse slot limits in Area 2C that the imposition of a protected slot will increase the number and average weight of released fish.

2.5.2 Results

The differing harvests under each scenario resulted in substantially different projections of removals. Under the low harvest scenario that assumes the reverse slot limit will not entice more anglers to keep a second fish, projected removals ranged from 1.461 Mlb to 1.994 Mlb for the range of size limits considered (Table 10a). Under the low scenario, there are several different reverse slot limits with projected removals at or below the 1.66 Mlb allocation associated with the Status Quo TCEY; no reverse slot limits are below the catch allocation associated with the Reference TCEY. Under the high harvest scenario, projected removals ranged from 1.891 Mlb to 2.456 Mlb (Table 10b). Under the high harvest scenario, projected removals are above both allocations for all reverse slot limits analyzed.

The results of these two scenarios are not presented as a choice, but rather to show the results of uncertainty in the calculations. The projections are highly sensitive to the proportion of second fish retained, and we lack the history with this management measure to say with reasonable certainty how many more anglers would retain a second fish. We also lack information to evaluate the level to which anglers may attempt to high-grade under such restrictions, which may result in substantial differences between predicted versus observed average weights. Our recommendation is to view these results as two extremes outlining a plausible range of projections.

2.6 Reverse Slot Limit Combined with a Maximum Size Limit and Tuesday Closures

2.6.1 Approach

As outlined above, this measure would combine a reverse slot limit on one fish with the status quo maximum size limit (28 inches) or a maximum size of 26 inches on the second fish. This regulation is functionally similar to a maximum size limit on both fish but provides anglers with the potential of harvesting one halibut of exceptional size. This management measure also provides flexibility in the number of closed Tuesdays. All other status quo management measures would remain in place.

The above scenarios bracket a range of plausible assumptions; a reverse slot limit has never been implemented in Area 3A and no empirical data exist on how the fishery might respond to such a regulation. This regulation limits the size of the fish that, under status quo regulations, can be of any length. It was assumed that restricting the length of both fish would increase the incentive to harvest two fish, thereby the number of fish harvested.

To provide information that is better suited for decision making, this scenario represents a moderate approach, bracketed between the low and high harvest scenarios outlined in section 2.5.1. The 2019 preliminary effort was used as the projected effort for 2020, as was the time series forecasts of HPUE. This approach then used the proportion of second fish from 2013, the last year before implementation of a size limit on one fish. Implementation of the maximum size limit on one fish in 2014 resulted in immediate and substantial decreases in HPUE and the proportion of second fish in subareas with large fish available (Webster and Powers 2019). It should be noted that there is still a considerable amount of uncertainty in this approach. Under status quo management measures, harvest (number of fish) forecasts range from 132,453 fish under the low harvest to scenario, to 158,674 fish using this moderate approach, to 174,415 fish under the high harvest scenario.

Effects of Tuesday closures were applied to this moderate harvest scenario following the methods outlined in Webster and Powers (2019).

The average weight of the first fish was projected exactly as was done in section 2.5.1. The average weight of the second fish was calculated as the average weight of U26 or U28 fish in 2013, allowing for the possibility that there may be additional high grading with the more restrictive size limits on both fish. There were no U26 fish caught in 3A and landed in Gustavus or Elfin Cove (G3A) in 2013, therefore, the average weight of U26 fish in Yakutat, the nearest port to this fishing area, was applied to G3A. The overall average weight for all sizes of fish was calculated as a weighted mean of the first and second fish, where the weighting factors were the projected proportions of first and second fish.

Projections were made for lower size limits ranging from 35-60 inches (U35-U60) and upper limits ranging from 60-80 inches (O60-O80). The lack of experience with this measure created another problem, namely there were no empirical mean weight data to correct the predictions to current conditions. These data were corrected using the factor developed in the low harvest scenario outlined in section 2.5.1. Finally, the yield projections were inflated by a factor of 4% to account for release mortality (see Section 2.5).

2.6.2 Results

The harvest scenario used for this analysis projects 158,674 fish will be removed under status quo Tuesday closures (5). For a size limit of 28 inches on one fish (status quo) and a reverse slot on the other fish, projected removals ranged from 1.563 Mlb to 2.428 Mlb for the range of size limits and Tuesday closures considered (Appendix Table A1a-o). For a size limit of 26 inches on one fish and a reverse slot on the other fish, projected removals ranged from 1.462 Mlb to 2.308 Mlb for the range of size limits and Tuesday closures considered (Appendix Table A2a-o). For both 26 and 28 inch size limits on one fish, there are several different combinations of reverse slot limit limits and Tuesday closures with projected removals at or below the 1.66 Mlb allocation associated with the Status Quo TCEY (Tables 11 & 12) with workable lower limits ranging from 4 – All Tuesdays closed at lower slots of 35 – 44 inches. No combinations of reverse slot limits, maximum sizes on the second fish, and Tuesday closures are below the catch allocation associated with the Reference TCEY.

The results of the two scenarios in section 2.5.1 illustrate the uncertainty in these calculations. In this section, we use an approach that incorporates these two scenarios into a single projection to aid in the decision making process. Still, the projections are highly sensitive to the proportion of second fish retained, and we lack the history with this management measure to say with reasonable certainty how many more anglers would retain a second fish. We also lack information to evaluate the level to which

anglers may attempt to high-grade under such restrictions, which may result in substantial differences between predicted versus observed average weights. Our recommendation is to view this as one plausible scenario, while considering the results in section 2.5 (Tables 10a & 10b; status quo Tuesday closures under low and high harvest scenarios, respectively) relative to Appendix Table A1f (status quo Tuesday closures under moderate harvest scenario).

Finally, the harvest reductions under each scenario of closed days represent the maximum expected reduction in the number of fish harvested (Webster and Powers 2019). A day of the week closure would be unlikely to achieve the maximum reduction in halibut harvest because of the potential for displaced anglers to book alternate dates either on the same vessel or another vessel with available space. There is a substantial amount of latent capacity on charter vessels in Area 3A (Marrinan and Fey 2017).

2.7 Reverse Slot Limit Combined with a Maximum Size Limit of 26 inches and Additional Closure Dates

2.7.1 Approach

This measure would combine a reverse slot limit on one fish, a maximum size limit of 26 inches on the second fish, a closure of all Tuesdays, and additional closure dates on Mondays or Thursdays. All other status quo management measures would remain in place.

The scenarios in section 2.5 bracket a range of plausible assumptions, because a reverse slot limit has never been implemented in Area 3A, and no empirical data exist on how the fishery might respond to such a regulation. To provide information better suited for decision making, this scenario uses the moderate approach outlined in section 2.6.1. The 2019 preliminary effort was used as the projected effort for 2020, as was the time series forecasts of HPUE. This approach then used the proportion of second fish from 2013, the last year before implementation of any size limit. Effects of Tuesday closures and additional closure dates on Mondays or Thursdays were applied following the methods outlined in Webster and Powers (2019) and Section 2.2.1.

The average weight of the first fish was projected exactly as was done in Sections 2.5.1 and 2.6.1. The average weight of the second fish was calculated following the same methods used in Section 2.6.1.

Projections were made for lower size limits ranging from 35-60 inches (U35-U60) and upper limits ranging from 60-80 inches (O60-O80). As outlined in previous sections, these projections were adjusted using the factor developed in the low harvest scenario to correct fish size to current conditions and the yield projections were inflated by a factor of 4% to account for release mortality.

2.7.2 Results

The harvest scenario used for this analysis projects 143,622 fish will be removed with all Tuesdays closed and no additional closure dates. For the addition of Monday closures (1 – 13 or all Mondays) with a reverse slot on one fish and a maximum size of 26 inches on the other fish, projected removals ranged from 1.211 Mlb to 1.909 Mlb for the range of size limits and closure dates considered (Appendix Table A3a-o). For the addition of Thursday closures (1 – 13 or all Thursdays) with a reverse slot on one fish and a maximum size of 26 inches on the other fish, projected removals ranged from 1.193 Mlb to 1.909 Mlb for the range of size limits and closure dates considered (Appendix Table A4a-o). For either day of the week, there are combinations of reverse slot limits and closure dates with projected removals at or below the 1.24 Mlb allocation associated with the Reference TCEY (Tables 13b & 14b). For Mondays, 13 closure dates would allow for a U35O80 fish and all Mondays closed would allow for a U35O66 fish. For Thursdays, 12 closure dates would allow for a U35O78 fish, 13 closure dates would allow for a U35O72 fish, and all Thursdays closed would allow for a U35O64, a U36O70, or a U37O80 fish. There are many combinations of reverse slot limits and Monday or Thursday closures at or below the catch allocation associated with the Status Quo TCEY (Tables 13c & 14c).

As indicated in section 2.6, the results of the two scenarios in section 2.5 illustrate the uncertainty in these calculations. In this section, we use a single approach that incorporates the two harvest scenarios into a single projection to aid in the decision making process. Still, the projections are highly sensitive to the proportion of second fish retained, and we lack the history with this management measure to say with reasonable certainty how many more anglers would retain a second fish. We also lack information to evaluate the level to which anglers may attempt to high-grade under such restrictions, which may result in substantial differences between predicted versus observed average weights. Our recommendation is to view this as one plausible scenario, while considering the results in section 2.5. Furthermore, it is important that the Council considers the potential that the maximum effect of day of the week closures may not be achieved as there is a substantial amount of latent capacity in Area 3A and anglers may be able to rebook on alternative days of the week (Marrinan and Fey 2017).

2.8 One-Fish Bag Limit, No Size Limit

2.8.1 Approach

This measure would combine a one fish bag limit, with no size limit, with all other status quo regulations.

The biggest challenge is estimation of the average weight under such a regulation. When the Area 2C charter fishery went from a two-fish bag limit with a maximum size limit on one fish (32 inches) to a one-fish bag limit with no size limit in 2009, the average weight increased 20% from the previous year, and increased another 13% in 2010 under the same regulation. The total increase in average weight over those two years was 36%. Under a one-fish bag limit, it is expected that anglers will high-grade to get the largest fish possible; the resulting increase in average weight will offset the decrease in the number of fish harvested to an unknown degree.

There are no empirical data from a fishery under a one-fish bag limit in Area 3A to use to predict the degree anglers may high-grade. It is also questionable whether the data from Area 2C is applicable to Area 3A, but the increase in average weight seen in 2009 and 2010 may be indicative of what is possible. There are many plausible approaches to predict average weight, with no clear way to decide which is the most accurate. The analysis looked at the average weight of all sizes of fish in 2019 and the average weight of O28 fish in 2019. Three average weight scenarios were considered. The first scenario used the average weight of O28 fish in 2019. The second used the average weight of O28 fish and an inflation factor of 20% due to high grading. A 20% increase was considered plausible based on the experience from Area 2C. The final scenario looked at the average weight of all sizes of fish from 2019 and included a 36% inflation factor due to high grading. Again, this was considered plausible based on observed changes in average weight relative to all sizes of fish in 2C when the bag limit was reduced to one fish.

It is not possible to tell from biological sampling data which fish were “first” fish, much less which fish were caught by which angler. Length data are obtained from fish or their filleted carcasses, where the fish from different anglers are mixed and the anglers are not present or can’t tell which fish belong to whom. Because there is a size limit on one fish of 28 inches, it was assumed that all fish over 28 inches were “first” fish and might emulate conditions under a one fish bag limit. This assumption is an approximation, as there may have been charter trips where some anglers two fish under the size limit. Under a one fish bag limit, there may be additional incentive to high grade, still there will be anglers who harvest a smaller (less than 28-inch) fish. As a method to estimate average weight, this method seems as good as any for generating a plausible estimate.

For all scenarios, the projected harvest was based on the status quo harvest forecast under a two-fish bag limit (Webster and Powers 2019), reduced by the 2020 forecast of the proportion of second fish in the harvest. It is assumed that a one fish bag limit will not affect effort in Area 3A. The average weight of fish under 28 inches was 5.3 lbs (net weight) in 2019; it is unlikely that the inability to harvest a fish of that size will incentivize an increase in days fished to harvest the same numbers of fish or lead to a

reduction in angler effort due to the more restrictive bag limits. Most likely, any changes due to angler behavior will be offset and result in similar levels of harvest to the status quo forecast.

Harvest projections were multiplied by each average weight option to obtain the projected yield under each scenario, and yields were inflated by 2% to account for release mortality. As with the inflation factor for a reverse slot limit, this number was selected arbitrarily, as there were not data upon which to base an estimate. 3A has never had a one fish bag limit, but release mortality would be assumed to be higher than status quo given the high grading expected under a one fish bag.

2.8.2 Results

The forecast proportions of second fish varied by subarea, with an overall average of 36%. After removing the second fish, the harvest forecast was 84,166 fish. The projections of charter removals under the three scenarios ranged from 1.815 Mlb to 2.211 Mlb (Table 15), all above the Reference TCEY catch allocation and the Status Quo TCEY catch allocation. Use of the O28 average weight from 2019 and the average weight of all sizes of fish from 2019 with a 36% inflation for high grading resulted in similar projections of removals.

As with the reverse slot combined with a maximum size limit on one fish management measure, it was not possible to identify the most accurate projection for this measure. The projections are highly sensitive to the average weight, and average weight cannot be predicted under this measure because it is not possible to predict angler behavior or the degree of high grading that will occur. Therefore, these options are presented not as a choice, but to illustrate the range of uncertainty associated with this management measure.

2.9 One-Fish Bag Limit with Reverse Slot Limit Combine with Tuesday Closures

2.9.1 Approach

This measure would combine a one fish bag limit, with a size limit, under a range of Tuesday closures with all other status quo regulations.

The projected harvest was based on the status quo harvest forecast under a two-fish bag limit (Webster and Powers 2019), reduced by the 2020 forecast of the proportion of second fish in the harvest (see section 2.8.1). It is assumed that a one fish bag limit would not affect effort in Area 3A. The average weight of fish under 28 inches was 5.3 lbs (net weight) in 2019; it is unlikely that the inability to harvest a fish of that size will incentivize an increase in days fished to harvest the same numbers of fish or lead to a reduction in angler effort due to the more restrictive bag limits. However, the addition of a reverse slot limit may have an impact on angler behavior that we are unable to account for in this analysis. There may be anglers who decide not to fish or to fish fewer days under such restrictive limits. There may be anglers who decide to fish additional days to increase the poundage they are able to retain.

Effects of Tuesday closures were applied to harvest following the methods outlined in Webster and Powers (2019). It was assumed that the proportional reduction of harvest from closing Tuesdays would be consistent regardless of whether the bag limit was one or two fish.

The average weight of the fish was projected exactly as was done for the reverse slot limit in Area 2C, but using length data from 2013, the last year without a size limit in Area 3A (Webster and Powers 2019). Projections were made for lower size limits ranging from 35-60 inches (U35-U60) and upper limits ranging from 60-80 inches (O60-O80). The lack of experience with this measure created another problem, namely there were no empirical mean weight data to correct the predictions to current conditions, as was done with the status quo measures (Webster and Powers 2019). However, imposition of a U60-O60 size limit would be the functional equivalent of one fish of any size. To correct mean weight, the projections were adjusted by a single correction factor to make the projected yield under a U60-O60 reverse slot limit match the projected yield under a one fish bag limit with no size restrictions. The yield projections under average weight of O28 fish in 2019 with a one fish bag limit (section 2.8.1) was used to obtain this

correction factor. Correcting the yield was the functional equivalent of correcting mean weight because the harvest (number of fish) projections were the same.

The yield projections were inflated by a factor of 4% to account for release mortality.

2.9.2 Results

Implementation of a one fish bag limit with a reverse slot limit combined with Tuesday closures could be used to bring the removals below either allocation scenario (Appendix Table A5a-o). Under the Reference TCEY, there are workable options with a minimum of seven closed Tuesdays with lower limits from 35 – 38 inches and upper limits from 62 – 80 inches (Table 16b). Under the Status Quo TCEY, any number of closed Tuesdays could be used with combinations of lower slot limits ranging from 40 – 60 inches and upper slot limits ranging from 60 – 80 inches (Table 16c).

2.10 Status Quo with All Days of the Week Open and a Seasonal Closure Prior to May 16 or June 1 and After July 31

2.10.1 Approach

This analysis looked at changing the halibut season for the charter sector in 3A from the status quo (February 1 – December 31) to an opening date of either May 16 or June 1 and a closing date of July 31. This management measure would allow for harvest on all days of the week throughout the open season (status quo includes Wednesday closures for the entire year and 5 Tuesday closures). These projections incorporate all other status quo measures.

The analysis followed the same harvest projection procedures as the analysis for opening all days of the week (Webster and Powers, 2019; Section 4.4). Status quo regulations in Area 3A included a year-round closure of the charter fishery on Wednesdays, as well as five Tuesdays closed (three in July and two in August). The analysis for opening all days relied on complete logbook data for 2014, the last year in which the fishery did not have any daily closures. The analysis proceeded by estimating the proportional effect of closed days in 2014 and applying those proportional effects to the harvest forecast for 2020. Estimated harvest for the entire year with all days opened was 167,980 halibut; this was used as the base harvest to estimate seasonal closures.

The analysis then assumed that the proportions of harvest in past years occurring before and after the open season dates would be eliminated if those days were closed in 2020. The proportion of harvest occurring between May 16 and July 31 has been between 64.7% and 69.5% since 2010 while the proportion of harvest occurring between June 1 and July 31 has been between 58.5% and 64.6%. Reasons for past variability are unclear but may include changes in halibut regulations (i.e. day of week closures, annual limits), changes in other fishery regulations (i.e. salmon, lingcod, rockfish), and changes to the tourism industry. Therefore, we provide three possible scenarios for this analysis. These are not provided as a choice, but rather to bracket the range of plausible outcomes if this management measure were implemented. The first scenario uses the proportion of harvest in 2014; this year had the highest proportion of harvest during the proposed open seasons and was the most recent year with no closure days. The second scenario uses the 2016 proportion of harvest during the open season; this year had the lowest proportion of harvest during the proposed open seasons. Finally, 2018 proportions were used for projections as this is the most recent year with complete logbook data and may mimic current conditions.

Average weight under each size limit was calculated and corrected as described in section 2.1.1 and a 1.1% release mortality inflation factor was added to estimate removals.

2.10.2 Results

The potential reduction in harvest relative to status quo from opening all days of the week and implementing a shorter season ranged from 11.9 – 17.9% for an open season from May 16 – July 31 and 18.0 – 25.9% for an open season from June 1 – July 31, depending on the harvest scenario. The projected removals associated with the three scenarios for a season with all days of the week open from May 16 –

July 31 and all other status quo management measures ranged from 1.596 to 1.711 Mlb. Depending on the actual harvest, the removals may remain under the Status Quo TCEY catch allocation for these season dates. The projected removals for a season with all days of the week open from June 1 – July 31 ranged from 1.442 to 1.592 Mlb (Table 17). Under all three scenarios, projected removal is below the Status Quo TCEY catch allocation. Neither set of dates and none of the scenarios result in projections that are below the Reference TCEY catch allocation.

3. Implementation Considerations

3.1 Size Limits

There are no anticipated problems associated with implementation of a reverse slot limit or maximum size limit in Area 3A. Size limits have been used successfully in regulatory areas for several years. Maximum size limits and reverse slot limits are implemented for the charter halibut fishery to control the average weight of harvested fish. This type of regulation increases the number of fish discarded thereby increasing removals associated with discard mortality. Not only do these size limits generate additional regulatory (versus voluntary) discards, they also increase the average weight of released fish. The relative impact of size limits, in terms of release mortality and angler satisfaction, is expected to vary by subarea due to variation in the availability of large fish in the catch. For example, clients fishing in subareas where large fish are commonly caught would likely end up releasing relatively more fish above the maximum size limit or in the protected slot, and those fish would likely be larger. Although release mortality is higher under size limits, it is included in the estimates of removals, and is accounted for in the charter sector allocation.

Projections of charter removals associated with combination reverse slot limit and a maximum size limit in Area 3A were highly uncertain. Section 2.5 bracketed harvest between two plausible scenarios, while subsequent sections used a more moderate approach to aid in the decision making process. In addition, this measure combined with various status quo measures such as trip limits, annual limits, and daily closures, could make for a highly complex and difficult to understand regulatory package. Once implemented in concert with other measures, it could be difficult to separate the relative effects of each measure. This could potentially impair future analyses of regulatory measures in Area 3A.

3.2 Annual Limits

Annual limits were implemented in Area 3A in 2015 (5 fish) and 2016 – 2019 (4 fish). If annual limits are recommended for the charter fishery, it is crucial for enforcement purposes to ensure that the regulation be accompanied by a recording requirement similar to that implemented in recent years. Specifically, immediately upon retaining a halibut, charter anglers must record, in ink, the date, location (IPHC area), and species (halibut) on their harvest record. The harvest record is located on the back of the State of Alaska fishing license. For anglers not required to have an annual license, a harvest card can be obtained from the ADF&G website¹ or from local offices. Enforcement of the annual limit consists of checking anglers with halibut to make sure the harvest is recorded. It is expected that Guided Angler Fish (GAF) taken under the CSP would be exempt from the annual limit and recording requirement as these harvests accrue toward the IFQ fishery allocation. Under the CSP, GAF must be recorded in the logbook immediately upon retention. When checking anglers at sea or dockside, enforcement personnel should be able to deduct GAF from fish that count toward an angler's annual limit.

The license or harvest card is not submitted at the end of the year. Halibut harvest accounting by individual anglers would continue to be implemented through ADF&G charter logbooks. Logbooks require reporting of the number of halibut kept and released by individual anglers, as well as the angler's name and fishing license number. For anglers fishing under the authority of an ADF&G Permanent Identification (PID) or Disabled American Veteran (DAV) card, the PID or DAV number must be

¹ http://www.adfg.alaska.gov/static/license/sportlicense/pdf/sf_harvest_record_card.pdf

recorded. No number can be recorded for youth anglers not required to be licensed. Under the CSP, all anglers (including youth) are required to certify in the logbook that the reported number of halibut kept and released is correct.

Concerns have been expressed in previous years regarding effective enforcement and compliance with halibut annual limits. A chief concern is that unscrupulous anglers will obtain duplicate or multiple licenses. Once a harvest record is full, these anglers could print another copy of their license and thereby comply with the reporting requirement yet still violate the annual limit. However, ADF&G can merge licensing and logbook data to examine the number of fish harvested by individual anglers, regardless of the number of licenses, duplicates, PIDs, or DAVs they may have held. Although ADF&G is not responsible for enforcement of the annual limit, this capability allows us to evaluate and report on compliance with halibut annual limits to the Council or to enforcement agencies.

The 5-fish annual limit in 2015 was implemented without a recording requirement. Beginning in 2016, the annual limit was decreased to 4 fish and a recording requirement was implemented. Since 2015, 0.2% - 1.0% of licensed anglers have exceeded the annual limit, accounting for 0.2% - 0.6% of harvest by licensed anglers. In 2018, 65,587 licensed anglers harvested 128,830 halibut in 3A. Of those, 201 (0.3%) violated the annual limit and harvested 296 fish in excess of the annual limit which represented 0.2% of the total harvest by licensed anglers. Anglers in Lower Cook Inlet accounted for the majority of the fish over their annual limit (171), followed by Central Cook Inlet (49).

Another concern with annual limits is that compliance may be low among youth anglers. Youth anglers are not required to be licensed, but are still required to complete a harvest record upon harvesting a halibut. Although enforcement in the field would be no different for youth anglers, their annual harvests cannot be evaluated post-season using logbook data. However, youth anglers have made up only 5.2-5.8% of angler-trips in Areas 3A in recent years. As stated earlier, all unlicensed youth anglers would be required to report each halibut on a harvest record. Youth typically fish on charter boats with parents or other adults, who, along with the guide or deck hand, would be expected to remind them of recording requirements. It is likely the proportion of youth that violate annual limits is small.

3.3 Daily Closures

As mentioned earlier, the primary issue with daily closures is that the effect cannot be accurately predicted or evaluated. Daily closures are expected to reduce effort, and therefore their effect is confounded with any factors that affect effort (e.g., trip limits, economic trends). This analysis could only estimate the maximum potential reduction in halibut harvest but cannot predict possible changes in angler behavior, such as anglers booking alternate days. In 3A, with Wednesdays closed all year and five Tuesdays closed during the peak season, closure of additional days during the peak season (June through August) may be more effective than closure of a day or two here and there. With each additional day closed, there would be fewer days available to rebook and fewer charters available to take the displaced anglers.

Another impact of daily closures is the potential increase in the harvest of state-managed species such as salmon, rockfishes, sablefish, and lingcod. Some charter businesses are able to book anglers to catch other species, particularly salmon. Increases in harvest will likely intensify conservation concerns for these stocks.

Another consideration for daily closures is the potential effect on estimation of the current year's halibut harvest. Daily closures for a portion of the year may alter the distribution of harvest within the year. The preliminary estimates of harvest for the current year are based on logbook data for trips through July 31. The harvest through that date is expanded using the proportion of harvest through that date in prior years, around 67 – 75% in 3A. If daily closures are selected that reduce harvest in a manner that is not proportional to harvest over the season, future preliminary harvest estimates could be biased. We

recommend that if additional daily closures are implemented in 3A, that they be structured around the dates listed in Table 22 of Webster and Powers 2019, and Tables 2 and 4 of this report.

3.4 One-fish Bag Limit

As shown in Section 2.8, the projections of charter removals under a one-fish bag limit are sensitive to the average weight, but there is not enough experience or empirical data to indicate what average weight would be under this measure in Area 3A. If implemented, one consideration is that this measure could cause a shift in the distribution of effort and harvest from Cook Inlet and the North Gulf (Seward) to other parts of Area 3A with larger fish, such as Yakutat, Valdez, and Kodiak.

3.5 Seasonal Closures

The projections of charter removals under a shorter season are sensitive to the proportion of fish harvested during the proposed open and closed season in past years. If implemented, one consideration is that this measure could cause a shift in the distribution of effort and harvest into the open season. As with daily closures, the effect cannot be accurately predicted or evaluated. A shorter season is expected to reduce effort. This analysis could only estimate the maximum potential reduction in halibut harvest but cannot predict possible changes in angler behavior, such as anglers booking alternate days. With a shorter season, there would likely be less available space to rebook on alternative dates or with alternative businesses.

The analysis assumed that the proportions of harvest occurring before and after the seasonal closure dates for past years would be eliminated if those days were closed in 2020. There is some variability in these proportions over past years and results are sensitive to this variability. Reasons for past variability are unclear but may include changes in halibut regulations (i.e. day of week closures, annual limits), changes in other fishery regulations (i.e. salmon, lingcod, rockfish), and changes to the tourism industry. We provided three possible scenarios for this analysis. These are not provided as a choice, but rather to bracket the range of plausible outcomes if this management measure were implemented.

Another impact of a shorter season is the potential increase in the harvest of alternative species such as salmon, rockfishes, sablefish, Pacific cod, and lingcod. Some charter businesses are able to book anglers to catch other species, particularly salmon. Increases in harvest will likely intensify conservation concerns for these stocks.

Table 5. Area 3A projected harvest (upper table) and removals (lower table) for 2020 under **a range of maximum size limits on one fish in the bag limit and with Tuesday closed all year and Thursday closures ranging from zero to thirteen days or a Thursday closure for the entire season**. Projected removals assume the following status quo measures: **two fish bag limit – one of any size, limit of one trip per vessel and one trip per permit per day, Wednesday closure all year, 4-fish annual limit**. Projections include corrections for errors in estimation of average weight and an additional 1.1% release mortality by weight. The most liberal options below the Status Quo TCEY allocation are highlighted in dark grey; no options were below the Reference TCEY allocation.

Projected Harvest (number of fish)

Harvest	Number of Thursday Closures															All
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	All	
119,851	117,755	115,651	114,256	112,116	110,348	108,440	107,462	105,929	104,329	102,810	102,210	101,215	100,515	97,627		

Projected Charter Removals (Mlb)

Size limit	Number of Thursday Closures															All
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	All

Table 6. Estimated effects of **annual limits of two and three halibut** on Area 3A anglers and projected harvest for 2020 under a **28-inch maximum size limit on one of two fish in the bag limit, vessel trip limit, permit trip limit, Wednesday closure, and Tuesday closure on five days** in July and August. The percent of affected anglers is the portion of individual anglers that harvested more than each specified annual limit in 2018.

Annual Limit	Subarea								Area 3A
	CCI	EPWS	GlacBay	Yak	LCI	NGulf	Kod	WPWS	
Estimated percent of anglers affected by an annual limit:									
2	13.9%	6.2%	12.9%	17.5%	12.2%	6.5%	29.2%	4.6%	11.6%
3	9.6%	2.7%	2.3%	6.3%	9.2%	2.5%	13.7%	0.9%	7.0%
Estimated percent change in harvest relative to no annual limit:									
2	-11.2%	-5.8%	-9.5%	-14.2%	-10.3%	-5.6%	-20.8%	-3.9%	-9.7%
3	-4.6%	-1.8%	-1.4%	-3.8%	-4.4%	-1.6%	-6.6%	-0.6%	-3.6%
Projected harvest (number of halibut):									
2	22,887	4,534	1,444	3,426	48,322	28,407	5,589	5,052	119,660
3	24,595	4,726	1,573	3,842	51,488	29,620	6,589	5,223	127,656
4 (status quo)	25,773	4,811	1,596	3,992	53,872	30,095	7,058	5,256	132,453

Table 7. Area 3A projected harvest (upper table) and removals (lower table) for 2020 under a **range of maximum size limits on one fish in the bag limit and for annual limits ranging from two to four fish per year**. Projected removals assume the following status quo measures: **two fish bag limit, limit of one trip per vessel and one trip per permit per day, Wednesday closure all year, five closed Tuesdays**. Projections include corrections for errors in estimation of average weight and an additional 1.1% release mortality by weight.

Projected Harvest (number of fish)

Year	Annual Limit (number of halibut)		
	2	3	4 (status quo)
2020	119,660	127,656	132,453

Projected Charter Removals (Mlb)

Size Limit (in)	Annual Limit (number of halibut)		
	2	3	4 (status quo)
26	1.700	1.814	1.874
27	1.722	1.838	1.899
28	1.758	1.876	1.938
29	1.781	1.900	1.964
30	1.816	1.938	2.003

Table 8. Area 3A projected harvest (upper table) and removals (lower table) for 2020 under an **annual limit of three fish with a range of maximum size limits on one fish in the bag limit and Tuesday closures** ranging from zero to thirteen days or a Tuesday closure for the entire season. Projected removals assume the following status quo measures: **two fish bag limit – one of any size, limit of one trip per vessel and one trip per permit per day, and Wednesday closure all year.** Projections include corrections for errors in estimation of average weight and an additional 1.1% release mortality by weight. The one option below the Status Quo TCEY allocation is highlighted in dark grey; no options were below the Reference TCEY allocation.

Table 10. Projected charter removals (Mlb) for Area 3A in 2020 under **reverse slot limits on one fish ranging from U35O60 to U60O80, and a maximum size limit on the other fish of 28-inches with all other status quo management measures.** Projections are provided for two scenarios: a low harvest scenario (a) is based on proportions of second fish in the harvest and HPUE projected for 2020 under status quo regulations and average weight of second fish in 2019, and a high harvest scenario (b) is based on the proportions and average weight of second fish in the harvest and HPUE from 2013 (before size limits in Area 3A). Projections also include a 4% inflation factor for release mortality and a correction factor to tune mean weight values to current conditions. Dark shaded values in the low harvest scenario represent values that are below the Status Quo TCEY allocation; no values in the low harvest scenario are below the Reference TCEY catch allocation. No values in the high harvest scenario are below the Status Quo or Reference catch allocation.

a. Low Harvest Scenario: 132,453

	Upper Length Limit (in)

Table 11. Projected harvest (top) under combinations of **closed Tuesdays with a reverse slot limit on one fish and a maximum size of 28-inches (status quo) on the second fish**. Combinations of closed Tuesdays, lower reverse slot limits, and upper reverse slot limits with projected removals below the Status Quo TCEY catch allocation (bottom table) under a two fish bag limit. No projections were below the Reference TCEY catch allocation. Numbers in cells indicate number of closed Tuesdays. Cells with the most liberal combinations of closures and size limits are highlighted with a blue – yellow scale indicating 0 to all closed days. Projected removals include all other status quo management measures: **a limit of one trip per vessel and one trip per permit per day, Wednesday closure all year, and a 4-fish annual limit.**

a. Estimated harvest under reverse slot and variable closed Tuesdays

Table 17. Projected harvest and removals under three possible scenarios for proportion of fish harvested in season in Area 3A under **an open halibut season with all days of the week open**. Two options for halibut seasons were analyzed, May 16 – July 31 (top table) and June 1 – July 31 (bottom table). Projected removals include all other status quo management measures: **bag limit of two fish, maximum size of 28-inches on one fish, a limit of one trip per vessel and one trip per permit per day, and a 4-fish annual limit**. Dark shaded values represent values that are below the Status Quo TCEY allocation; the low harvest and recent harvest scenarios for an open season from May 16 – July 31 and all scenarios for a season from June 1 – July 31 are below the Status Quo TCEY allocation. No values are below the Reference TCEY catch allocation for any scenario or either proposed season dates.

Season dates May 16 – July 31

Base Year for Proportion of Harvest	Harvest	Removals (Mlb)
2014 (High Harvest)	116,744	1.711
2016 (Low Harvest)	108,763	1.596
2018 (Most Recent Harvest)	112,676	1.628

Season dates June 1 – July 31

Base Year for Proportion of Harvest	Harvest	Removals (Mlb)
2014 (High Harvest)	108,644	1.592
2016 (Low Harvest)	98,147	1.442
2018 (Most Recent Harvest)	103,786	1.503

APPENDIX I

Table A1. Projected charter removals (Mlb) for Area 3A in 2020 under a **two fish bag limit and reverse slot limits ranging from U35O60 to U60O80 with a range of Tuesday closures throughout the season**. Projected removals include all other status quo management measures: **a limit of one trip per vessel and one trip per permit per day, a 28-inch size limit on one fish, Wednesday closure all year, and a 4-fish annual limit**. Projections also include a 4% inflation factor for release mortality and a correction factor to tune mean weight values to current conditions. Harvest forecast under status quo closed Tuesdays (5) with a reverse slot on one fish is 158,674 fish. Dark shaded cells represent projections for the most liberal Tuesday closures, upper size limits, and lower size limits that do not exceed the 1.66 Mlb allocation associated with the Status Quo TCEY scenario.

a. No Closed Tuesdays, 28-Inch Second Fish

Table A2. Projected charter removals (Mlb) for Area 3A in 2020 under a **two fish bag limit and with a reverse slot limit on one fish ranging from U35O60 to U60O80 and a size limit of 26-inches on the second fish with a range of Tuesday closures throughout the season**. Projected removals include all other status quo management measures: **a limit of one trip per vessel and one trip per permit per day, Wednesday closure all year, and a 4-fish annual limit**. Projections also include a 4% inflation factor for release mortality and a correction factor to tune mean weight values to current conditions. Harvest forecast under status quo closed Tuesdays (5) with a reverse slot on one fish is 158,674 fish. Dark shaded cells represent projections for the most liberal Tuesday closures, upper size limits, and lower size limits that do not exceed the 1.66 Mlb allocation associated with the Status Quo TCEY scenario.

Table A3. Projected charter removals (Mlb) for Area 3A in 2020 under a **two fish bag limit with all Tuesdays closed, a reverse slot limit on one fish ranging from U35O60 to U60O80, a size limit of 26 inches on the second fish and a range of Monday closures throughout the season**. Projected removals include all other status quo management measures: **a limit of one trip per vessel and one trip per permit per day, Wednesday closure all year, and a 4-fish annual limit**. Projections also include a 4% inflation factor for release mortality and a correction factor to tune mean weight values to current conditions. Light shaded cells represent projections for the most liberal Monday closures, upper size limits, and lower size limits that do not exceed the 1.24 Mlb allocation associated with the Reference TCEY scenario. Dark shaded cells represent projections for the most liberal Monday closures, upper size limits, and lower size limits that do not exceed the 1.66 Mlb allocation associated with the Status Quo TCEY scenario.

Table A4. Projected charter removals (Mlb) for Area 3A in 2020 under a **two fish bag limit with all Tuesdays closed, a reverse slot limit on one fish ranging from U35O60 to U60O80, a size limit of 26 inches on the second fish and a range of Thursday closures throughout the season**. Projected removals include all other status quo management measures: **a limit of one trip per vessel and one trip per permit per day, Wednesday closure all year, and a 4-fish annual limit**. Projections also include a 4% inflation factor for release mortality and a correction factor to tune mean weight values to current conditions. Light shaded cells represent projections for the most liberal Thursday closures, upper size limits, and lower size limits that do not exceed the 1.24 Mlb allocation associated with the Reference TCEY scenario. Dark shaded cells represent projections for the most liberal Thursday closures, upper size limits, and lower size limits that do not exceed the 1.66 Mlb allocation associated with the Status Quo TCEY scenario.

a. No Closed Thursdays, All Tuesdays Closed, 26-Inch Second Fish

Table A5. Projected charter removals (Mlb) for Area 3A in 2020 under a **one fish bag limit and reverse slot limits ranging from U35O60 to U60O80 with a range of Tuesday closures throughout the season**. Projected removals include all other status quo management measures: **a limit of one trip per vessel and one trip per permit per day, Wednesday closure all year, and a 4-fish annual limit**. Projections also include a 4% inflation factor for release mortality and a correction factor to tune mean weight values to current conditions. Light shaded cells represent projections for the most liberal Tuesday closures, upper size limits, and lower size limits that do not exceed the 1.24 Mlb allocation associated with the Reference TCEY scenario. Dark shaded cells represent projections for the most liberal Tuesday closures, upper size limits, and lower size limits that do not exceed the 0.80 Mlb allocation associated with the Status Quo TCEY scenario.

a. No Closed Tuesdays, One Fish Bag Limit
