

Eastern Bering Sea snow crab assessment draft

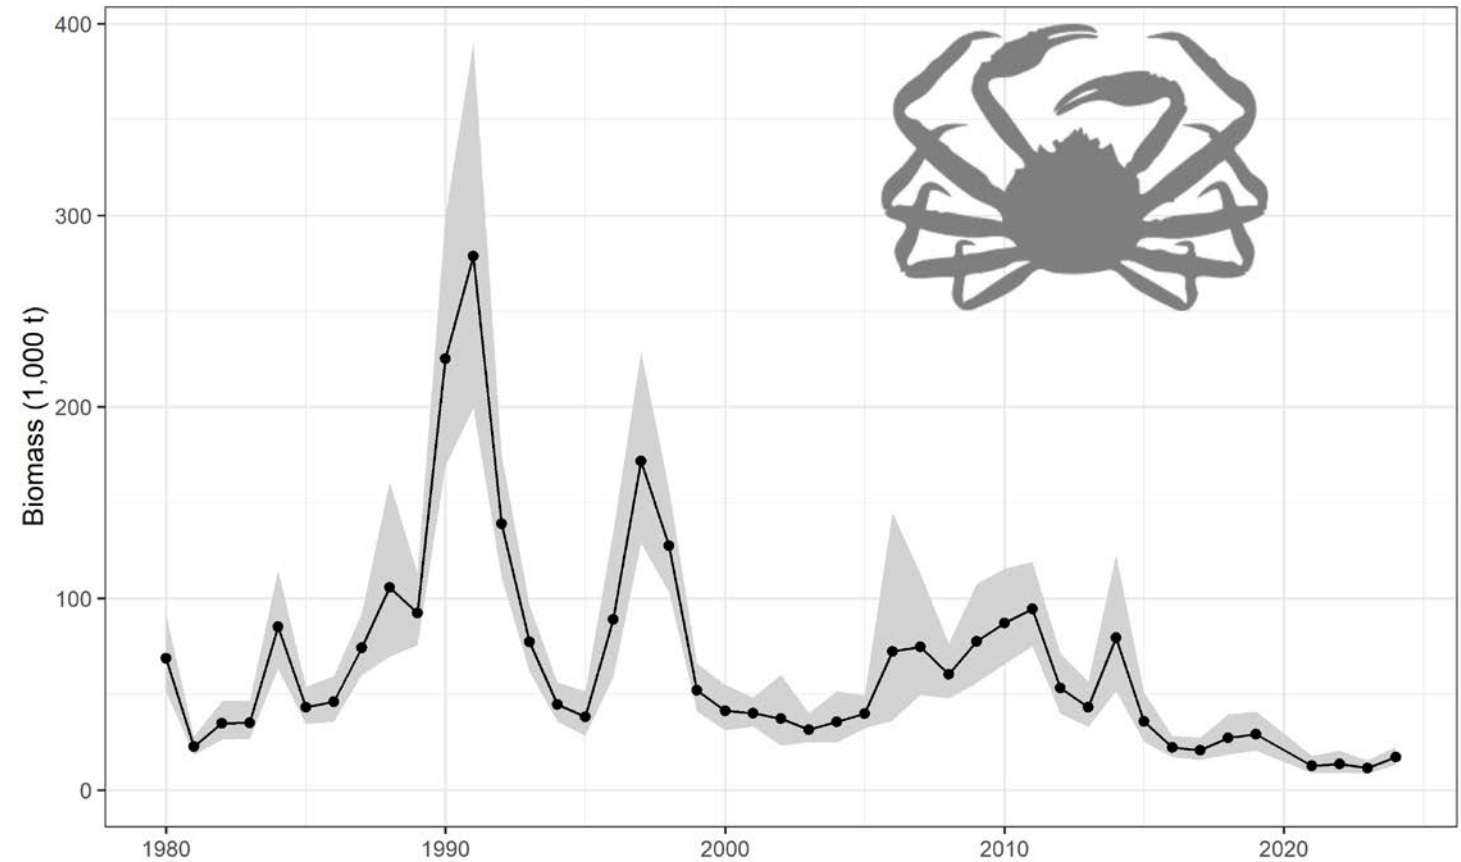

Cody Szuwalski

September 13, 2024

Big picture

- Small increase in commercial males
- Still 4th lowest on record
- 6% of the maximum observed
- 25% of the mean since 1980

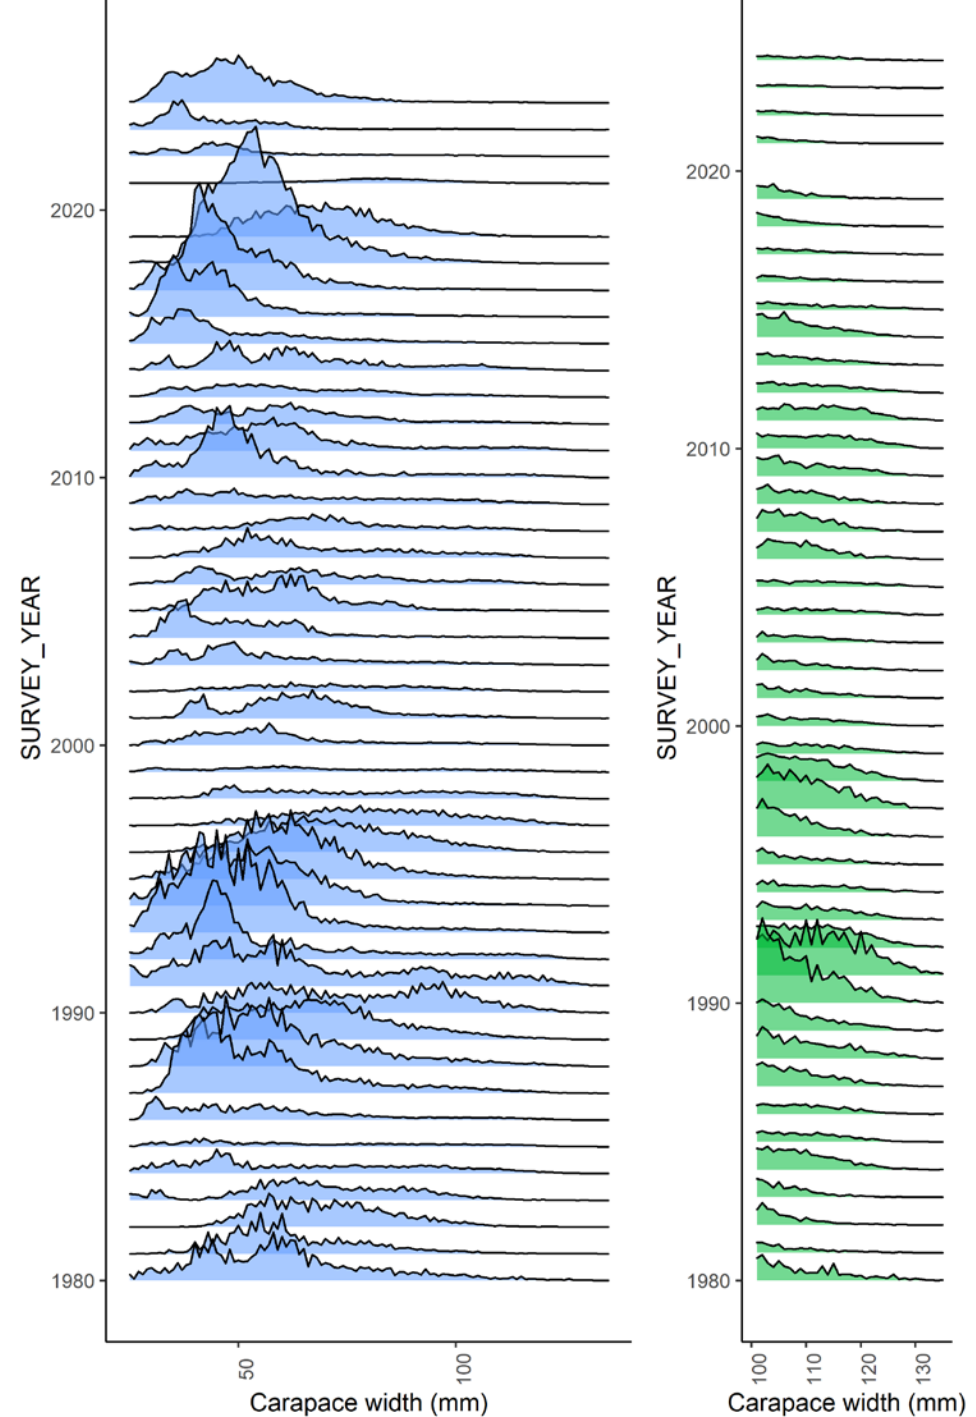

- Last 8 years are the lowest on record
 - In order: 2023, 2021, 2022, 2024, 2017, 2016, 2018, 2019

Big picture

- Small increase in commercial males
- Still 4th lowest on record
- 6% of the maximum observed
- 25% of the mean since 1980

 - In order: 2023, 2021, 2022, 2024, 2017, 2016, 2018, 2019
- Encouraging signs

Big picture

- Small increase in commercial males
- Still 4th lowest on record
- 6% of the maximum observed
- 25% of the mean since 1980

- Last 8 years are the lowest on record
 - In order: 2023, 2021, 2022, 2024, 2017, 2016, 2018, 2019
- Encouraging signs
- Surprising female results

Recommendations

- Reference points
 - Status quo tier 3 reference points too aggressive
 - Modified tier 3 reference points too conservative
 - **Tier 4 recommended**
- GMACS vs. survey
 - No immediate way to actually apply the exploitation rate associated with M given the estimated fishery selectivity
 - GMACS underestimates the large males considerably
 - Jittering issues also present with GMACS
 - **Use the survey estimates of males >101mm**

Year	Tier	BMSY	Males_com	Status	FOFL	OFL	Years	M
2023/2024	4_author	57.27	14.58	0.25	0.05	0.66	1982-2022	0.27
2023/2024	4_SSC	NA	16.56	NA	0.27	3.92	NA	0.27

Overview

- Review of key changes to dynamics
 - Probability of undergoing terminal molt
 - Exploitation rates on large males under status quo reference points
- Incorporating uncertainty into management targets
 - SBPR%
 - Currency of management
- Application in GMACS
 - Diagnostics
 - Fits and OFLs
- Management recommendations
 - Tier 3 vs 4
 - Model-based vs. observed estimates of biomass
- Ruminations on reproduction

SSC recommendations

- **SSC comment: The SSC requests that the Clark maximin re-analysis more closely follow the original analysis, which was carefully crafted to encompass a reasonable range of discrete stock productivities. Clark (1991) used both Ricker and Beverton Holt curves, used three curves intended to span a plausible range of steepness (0.50, 0.67, and 0.80), and excluded alternatives of 0.33 and 0.89 steepness. The SSC notes that FX% is the fishing mortality associated with an X percent reduction in spawning output per recruit (not percent reduction in stock size as shown in the draft document). It will be important to provide plots showing yield and the percent reduction in the different reproductive output measures as a function of fishing mortality. The SSC also requests that an exploitation rate be reported in addition to fishing mortality, which can be misleading because of the right-shifted selectivity curve for snow crab. This shift results in very few crab experiencing full-selection fishing mortality. Ideally, this analysis would use the parameters estimated in the GMACS operational model, rather than the snow crab research model. **
- **This has been done to the best of my ability in the time available and is detailed in appendix A.**
- **SSC comment: Concerning the GMACS assessment model, the SSC continues to recommend that the assessment author explore ways to incorporate the molt to maturity data in the model in a way that reflects the observation error associated with those estimates. An analysis in a GLMM modeling framework, which treats years as random effects, would provide smoother estimates, accommodate differing sample sizes by year and length, and deal appropriately with years in which data are missing. Another possibility that was suggested in the CPT report was to include the annual observed probabilities of terminal molt as data and then fit them, as in the Tanner crab assessment. **
- **Not addressed in this document.**
- **SSC comment: The SSC recommends that this model be brought forward in the fall but requests that an additional Tier 4 model be provided for comparison, as recommended in the Simpler Modeling Workshop report and requested in the SSC's June 2023 and October 2023 Reports. This additional model would use the random effects model (REMA) to smooth survey estimates and would not decrement with natural mortality. **
- **This is included in this document.**

SSC recommendations

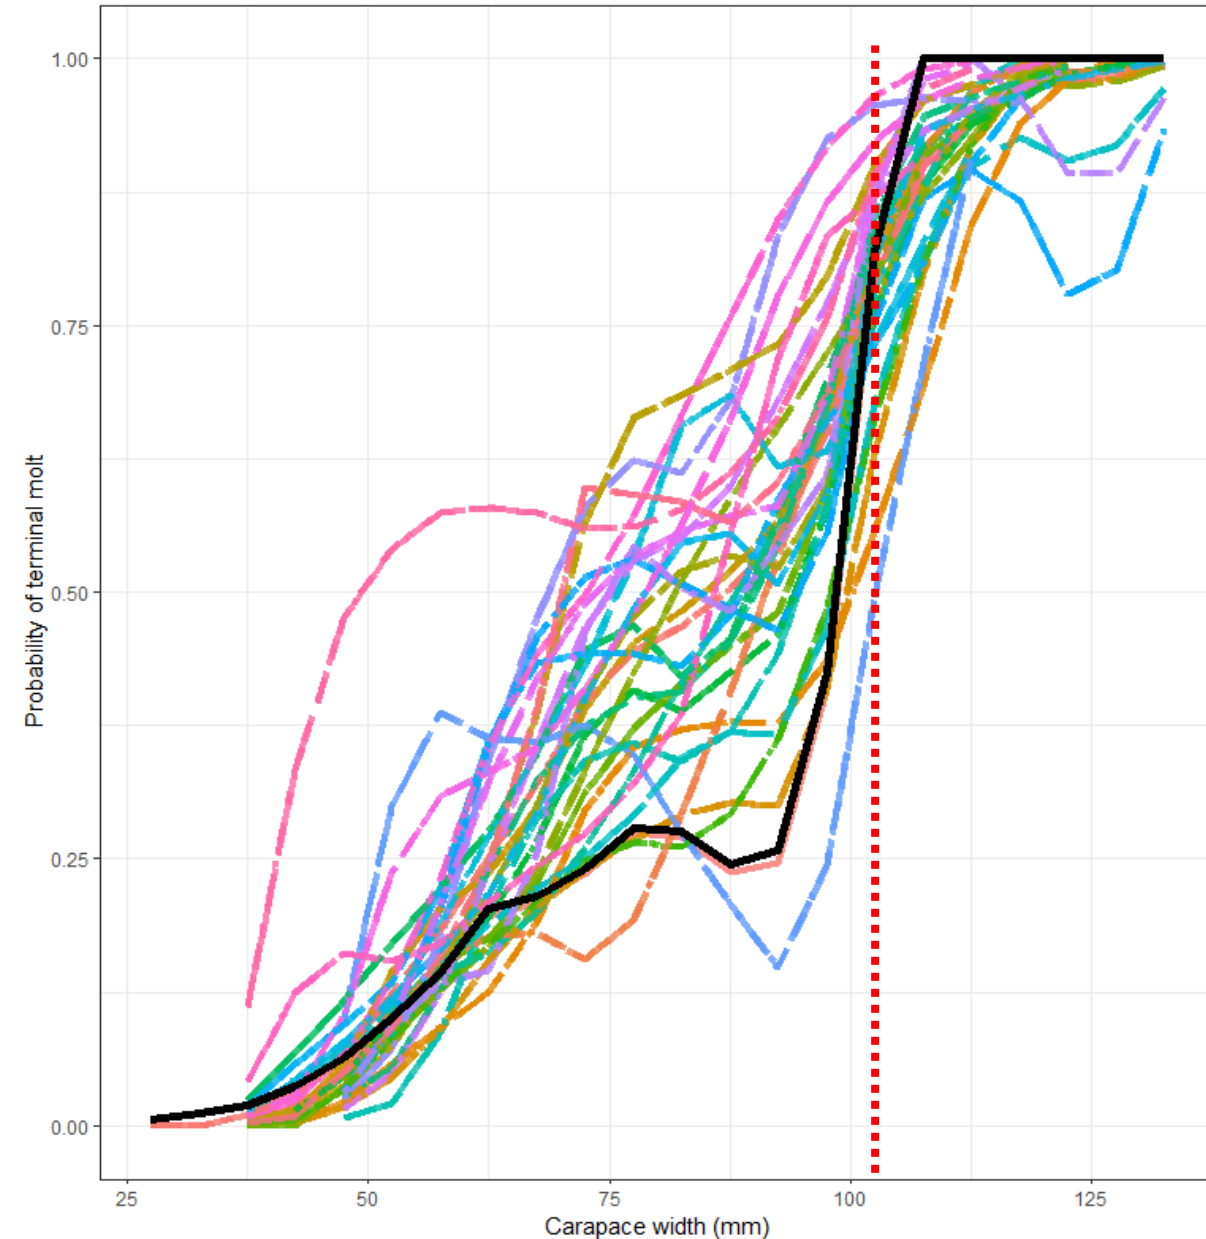

- Each of these points has been discussed to some extent at CPT meetings and will be addressed more thoroughly when time allows.

From Sept 2023:

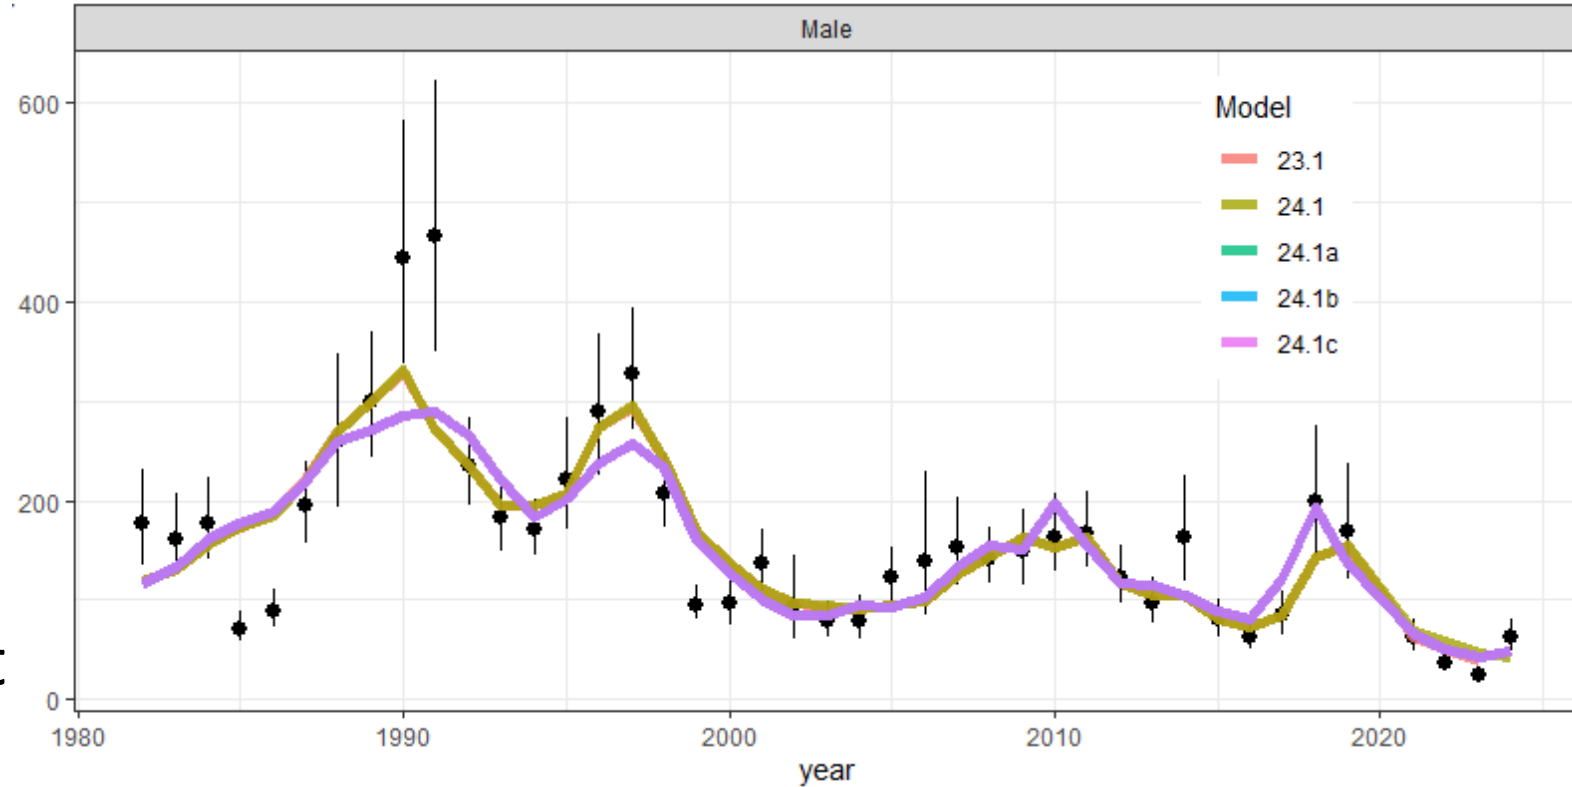

- **SSC comment: The SSC strongly supports the plans of the CPT to evaluate other metrics for reproductive output. The CPT may want to consider a multi-attribute measure of reproductive output. For example, both percent reduction in mature male biomass and percent reduction in large males could be evaluated as a function of fishing mortality.**
- **SSC comment: Figure 23 on page 73 of the SAFE report shows the decline in CPUE over a season by statistical area and year. This represents a kind of depletion experiment, suggesting that total mortality (Z) could be estimated from the linear parameters representing each line. This might help determine spatial patterns in F , indicate the natural bounds for F and M , and assist in determining stock status.**
- **SSC comment: Investigate whether there is information outside the assessment model (e.g., larval or post-settlement data) or in the model supporting estimated skewed sex-ratios at recruitment.**

Recent assessment changes

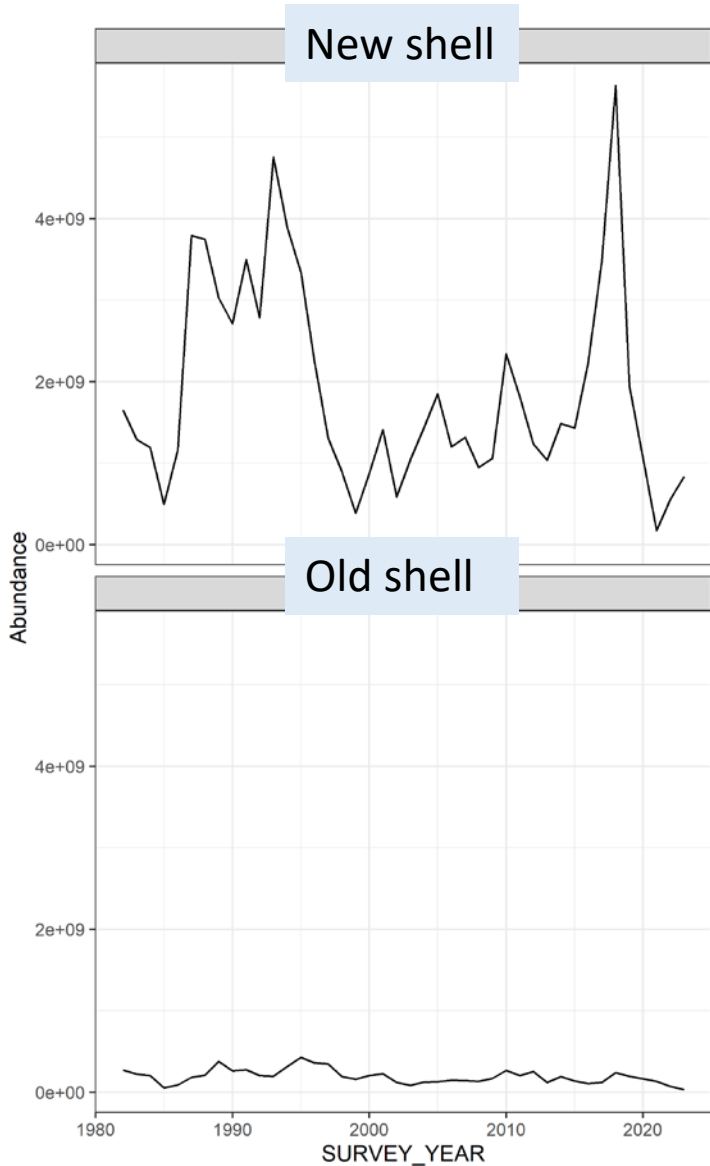

- Probability of undergoing terminal molt updated to reflect biology
- Status quo reference points and currency of management definitions would allow the capture of all large males.
- This happens because a small mature male is assumed equivalent to a large mature male.

- MMB time series to which the models are fit are the same and reflects morphometrically mature male biomass
- The distributions of the underlying population of numbers of mature males at size is drastically different

Preparing assessment data (MMB)

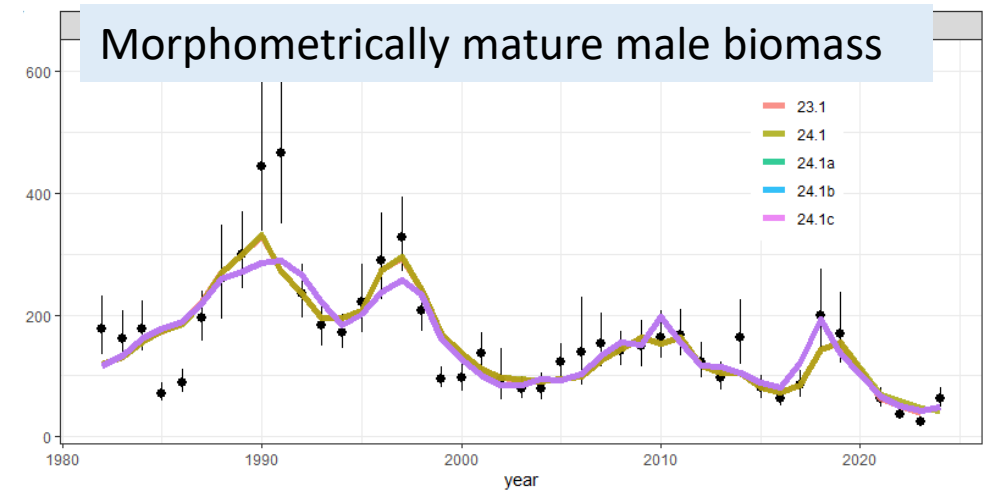

Weight at size

Weight at size

Index of immature animals not fit
Immature size composition data are fit

- MMB time series to which the models are fit are the same and reflects morphometrically mature male biomass
- The distributions of the underlying population of numbers of mature males at size is different

Are small mature males equivalent to large mature males in reproduction?

?=

Is it ok to take all the large males because the small males will get the job done?

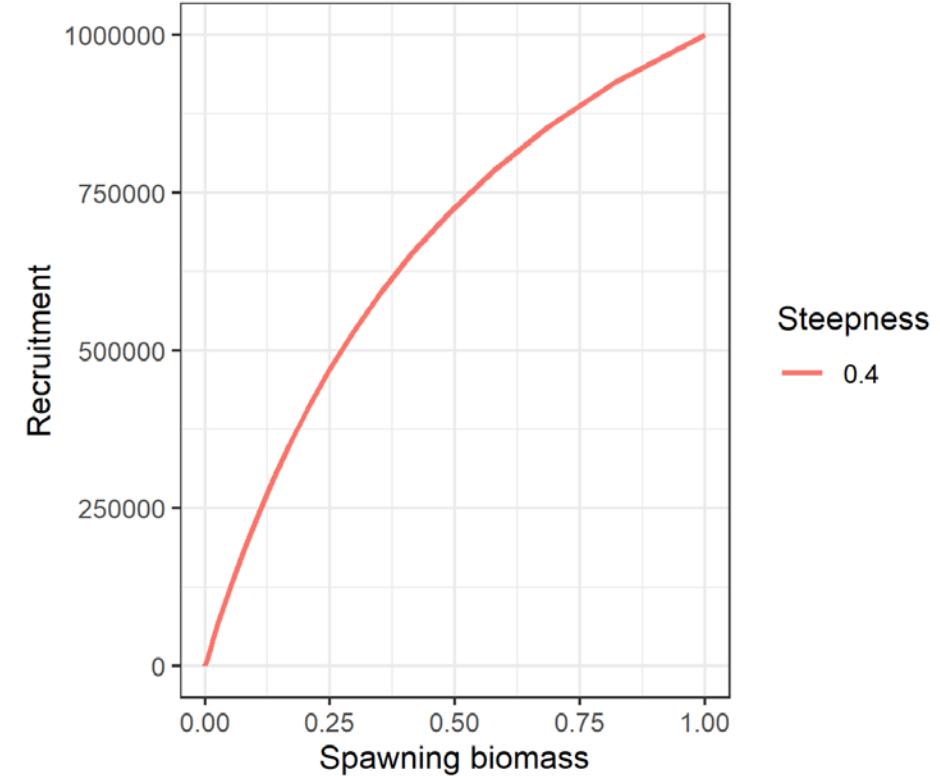

What we know

- Laboratory: Small males can mate with larger females (Watson, 1979)
- Laboratory: Small males are always outcompeted if large males are present (Comeau et al., 1998)
- In situ: Only males larger than 95mm carapace width were observed participating in mating in eastern Canadian waters (Conan and Comeau, 1986).

Given conflicting information, can we incorporate this uncertainty into management?

Maximum sustainable yield

- Given life history and equilibrium dynamics, a fishing mortality exists that will provide the maximum yield.
- Stock recruit relationships directly determine MSY.

Maximum sustainable yield

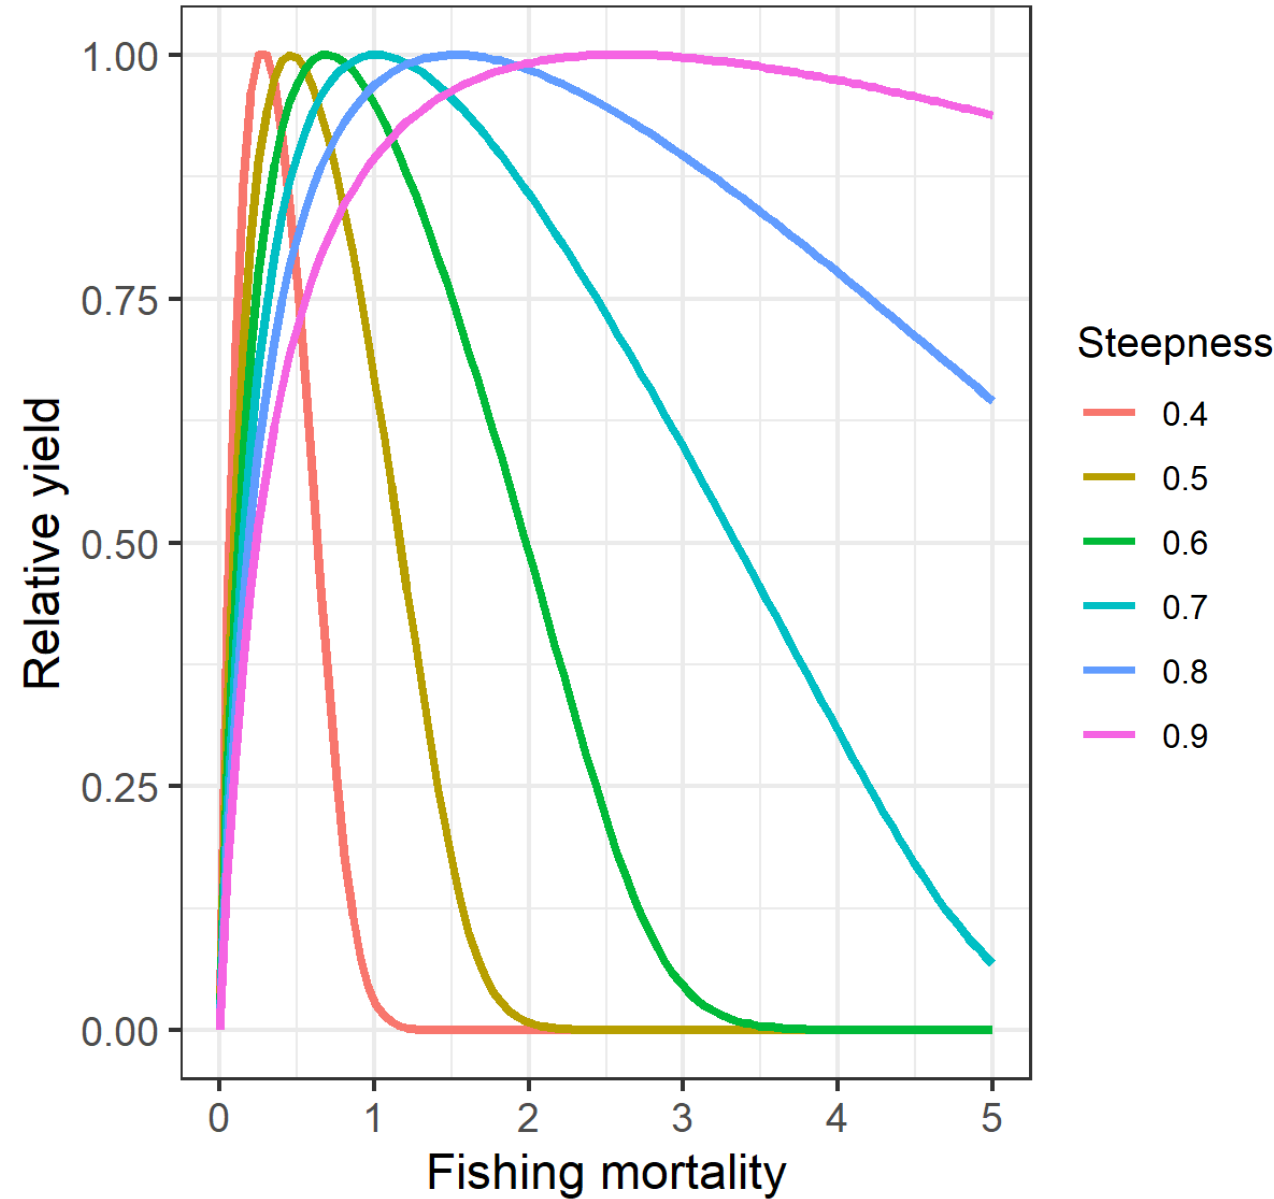

- Given life history and equilibrium dynamics, a fishing mortality exists that will provide the maximum yield.
- Stock recruit relationships directly determine MSY.
- The more recruitment provided for a given spawning biomass, the harder the stock can be fished.

Most stocks (including crab) do not display a stock recruit relationship

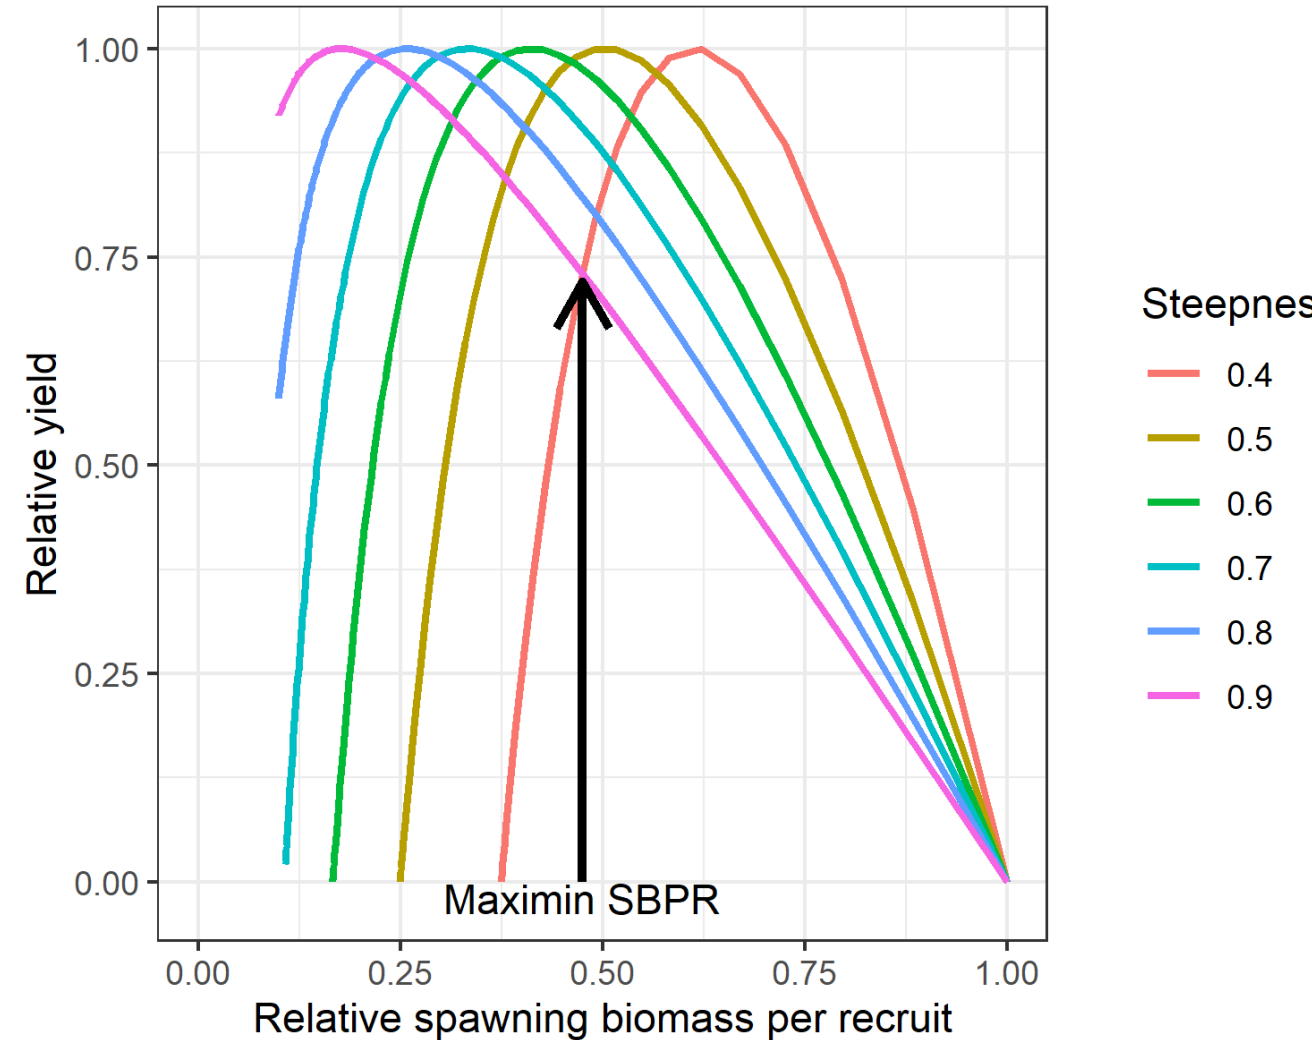

Bill Clark's good idea

- Identify a fishing mortality (and therefore spawning biomass) that produces 'pretty good yield' across a range of stock recruit relationship
- Maximize the minimum yield across scenarios

Bill Clark's good idea

- Identify a fishing mortality (and therefore spawning biomass) that produces 'pretty good yield' across a range of stock recruit relationship
- Maximize the minimum yield across scenarios

Can we incorporate uncertainty in
reproductive activity at size?

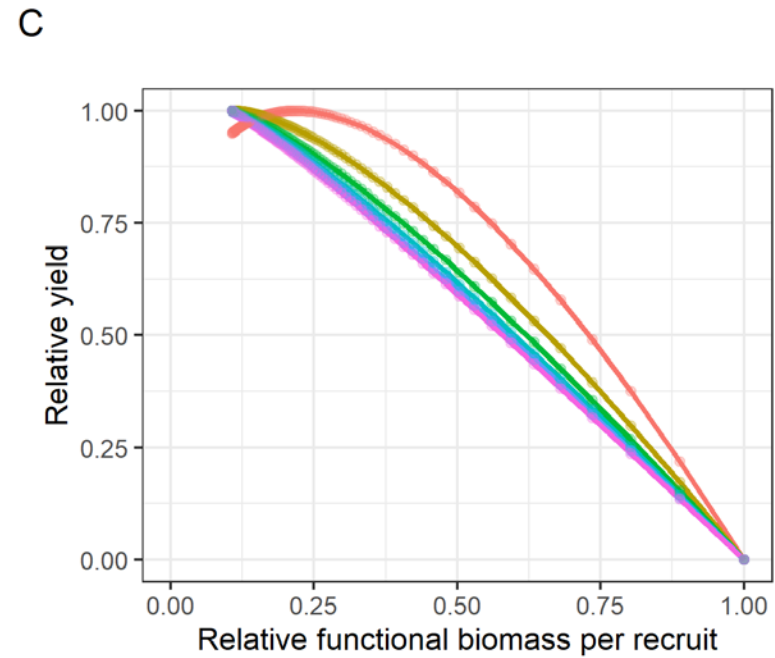

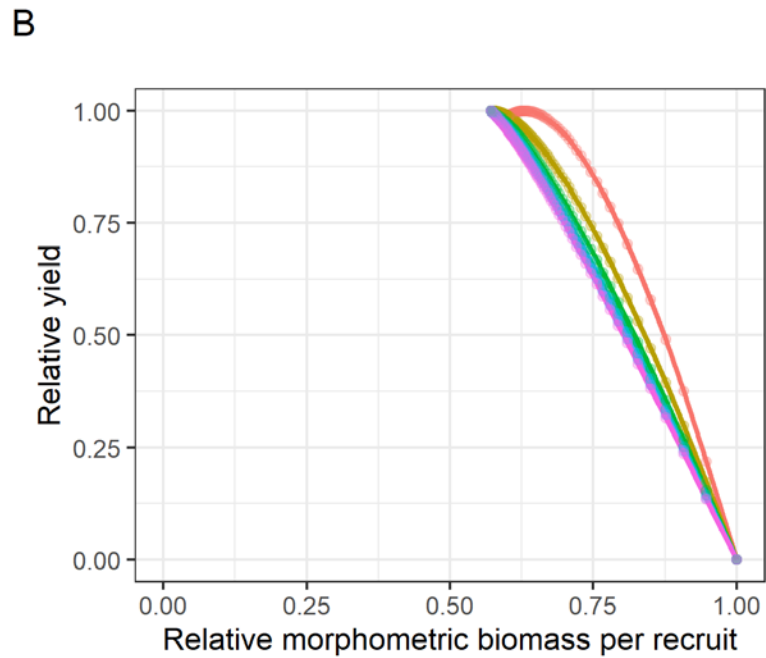

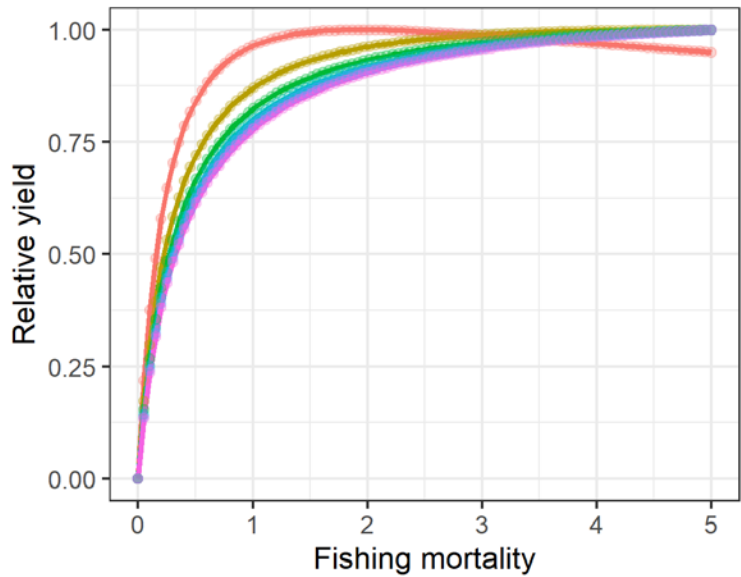

Can we incorporate this uncertainty into management?

- Repeat Clark's analyses, but with snow crab life history
 - Population dynamics model based on GMACS output
 - Recruitment dynamics based on Beverton Holt curve with steepness ranging from 0.4 to 0.9
 - Project forward to equilibrium for a given fishing mortality
 - Plot equilibrium yield relative to fishing mortality and different currencies of management

Can we incorporate this uncertainty into management?

- Repeat Clark's analyses, but with snow crab life history
- Add another axis to represent uncertainty in the size at which mature crab contribute to reproduction
- Scenarios differ in what sizes are used for 'spawning biomass' in recruitment and reference point calculations:
 - Morphometric maturity is determined by chela height
 - Functional maturity (>95 mm)
- Looking for a reference point that represents a compromise between these two hypotheses about reproductive dynamics

A Morphometric maturity determines recru

D Functional maturity determines recruits

Triangle represents the maximin solution when morphometric maturity drives dynamics.

Square represents the maximin solution when functional maturity drives dynamics.

Circle represents the maximin compromise between the hypotheses.

One GMACS model, three HCR configurations for consideration:

Model	Currency of management	SBPR%
24.1a	Morphometric mature biomass	35%
24.1b	>95mm mature biomass	35%
24.1c	>95mm mature biomass	45%

Assessment model

Process	Historical assumptions	Updated assumptions
Recruits	Equal sex ratio	Unequal sex ratios
Natural mortality	Constant with strong priors	Strong priors and time-block in 2018-2019
Growth	Piece-wise	Linear
Maturity	Single estimated ogive	Input yearly observations
Fishing mortality	Freely estimated	GMACS changed form
Fishery selectivity	Freely estimated	GMACS changed form
Survey selectivity	Logistic, BSFRF as survey	Non-parametric, BSFRF as priors

Model diagnostics

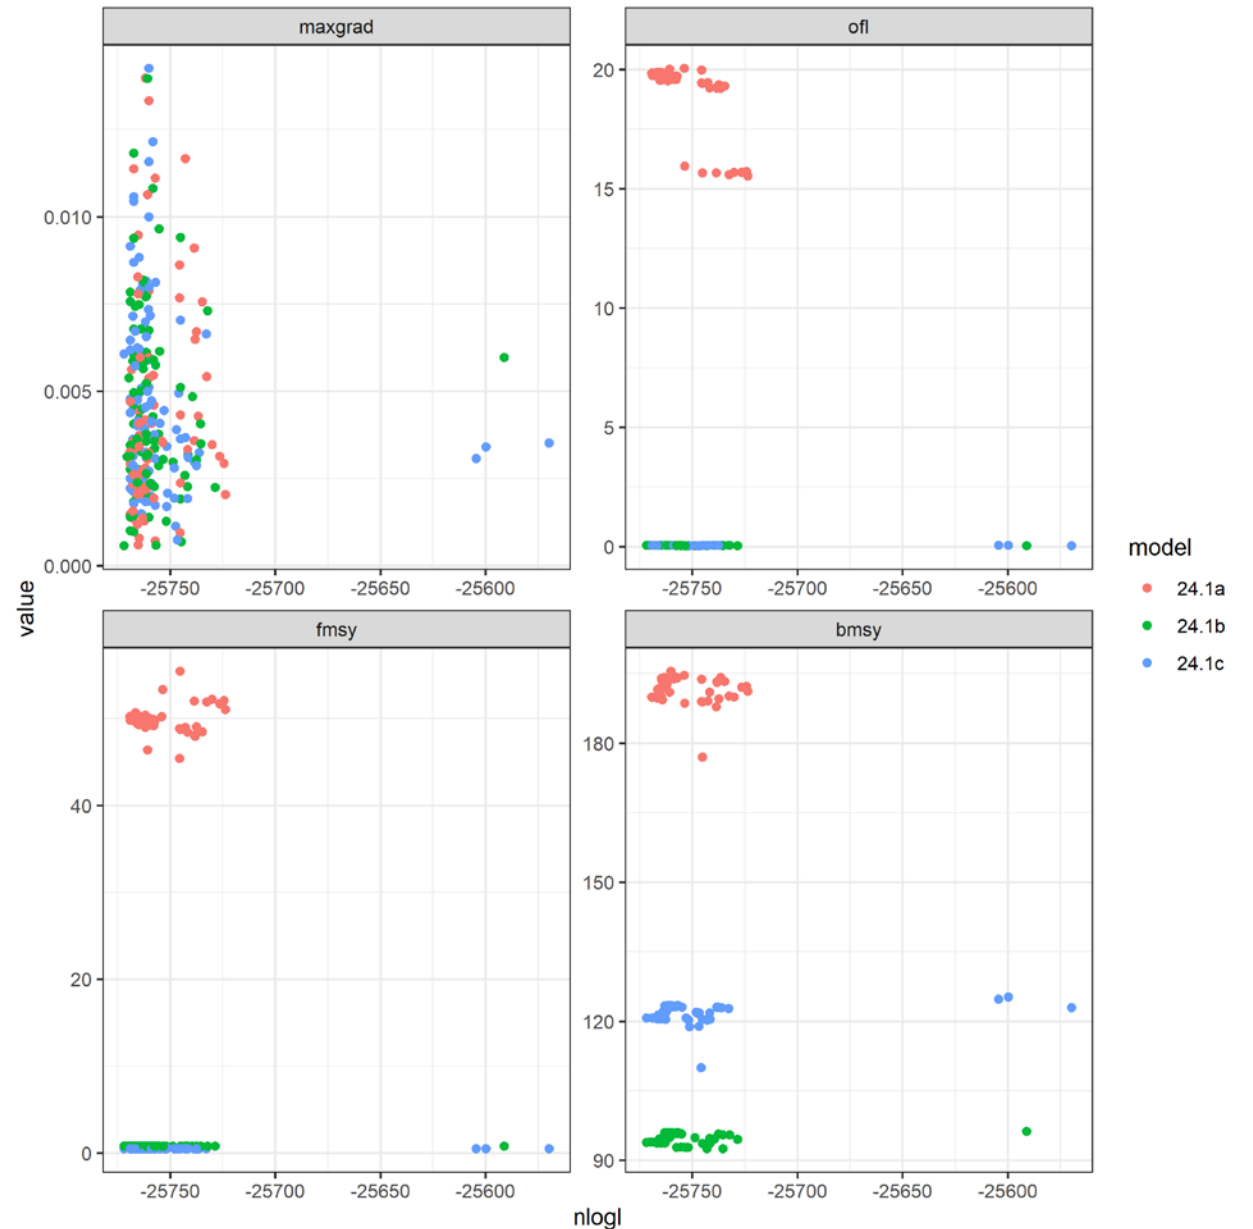

- Retrospective patterns are not concerning

Retrospective patterns in estimated mature male biomass for selected models.

Model diagnostics

- Retrospective patterns are not concerning
- Jittering patterns are concerning

Output of 100 jittered model fittings for selected models. Top left is the maximum gradient component, top right is the overfishing level, bottom left is F35, and bottom right is B35. Each dot represent an instance of a jittered fitted model and are colored based on the OFL resulting from that run.

Why so few large males?

2022

2023

2024

Why so few large males?

- Low recruitment
- High probability of terminal molt

Model Summary

- Things I like
 - Data sources are modeled in ways that represent the biology well
 - (the move to non-parametric survey selectivity + realistic probability of terminal molt was what was needed)
- Things that could use work
 - Survey selectivity estimates smoothness
 - Poor fits to large males recently
- Things I hope to explore
 - Modifications to GMACS to accept an input F for tier 4 rules
 - Sensitivities to explore estimates of fishery selectivity
 - Estimating probability of terminally molting with priors
 - Why is the jitter jittery
 - density dependence in probability of terminal molt and the implications for management

Harvest control rules

GMACS biomass + tier 3

24.1a: Morphometric mature biomass; B35%

24.1b: >95mm mature biomass; B35%

24.1c: >95mm mature biomass; B45%

Model	MMB	B35	F35	FOFL	OFL	M	avg_rec	Status

FEDERAL CLOSURE

Survey biomass + tier 4

- 4_author:
 - >101 mm mature males;
 - sloped HCR; FMSY = M;
 - BMSY = avg biomass 1982-2022;
 - decrement survey biomass by M to fishery
- 4_ssc:
 - >101 mm mature males;
 - FMSY = M

Year	Tier	BMSY	Males_com	Status	FOFL	OFL	Years	M
2023/2024	4_author	57.27	14.58	0.25	0.05	0.66	1982-2022	0.27
2023/2024	4_SSC	NA	16.56	NA	0.27	3.92	NA	0.27

Tier 4 retrospective (>101mm)

(Tier 4 w/in GMACS might bring these closer together)

Federal vs. State HCERS

Biomass	FMSY	BMSY	Currency	OFL	comments
GMACS 24.1a	F35%	B35%	Morphometric	19.60	Only 6.28 kt of the OFL is industry-preferred, 7.9 kt is retained; the rest of the OFL is discard. Even a 65% buffer allows for the removal of all the large males.
GMACS 24.1b	F35%	B35%	>95mm	0.05	Overfished fishery in 2014-now; closures 2018, 2020-present
GMACS 24.1c	F45%	B45%	>95mm	0.05	Overfished fishery in 2014-now; closures 2018, 2020-present with worse status
GMACS (not shown)	M	Avg biomass	Morphometric	0.45	Fishery mortality + natural mortality != FMSY exploitation rate
GMACS (not shown)	M	Avg biomass	>95mm	0.05	Fishery mortality + natural mortality != FMSY exploitation rate
Survey 4_author	M	Avg biomass	>101mm	0.66	Only close the fishery the last 3 years, but retrospective catches more conservative than TAC
Survey 4_SSC	M	NA	>101mm	3.92	No slope/status in HCR == no mechanism for closure; No decrement between survey and fishery

BUFFER

- CPT recommended 20% in 2023
- SSC recommended 50% in 2023
- I recommend 20% in 2024, contingent upon model/tier selection

Are small mature males equivalent to large mature males in reproduction?

- We are going to spin our wheels until we have resolution on whether or not the small males are important in reproduction
- Trying to identify a 'risk neutral' compromise resulted in what seems to be very conservative management
- Are there differences between population sustaining reproduction and fishery sustaining reproduction?
- Can we talk about status of the fishery differently than the status of the population?

OPTIMISM

CAUTION

Long slow decline for lg males

OPTIMISM

CAUTION

Density dependence in maturity?

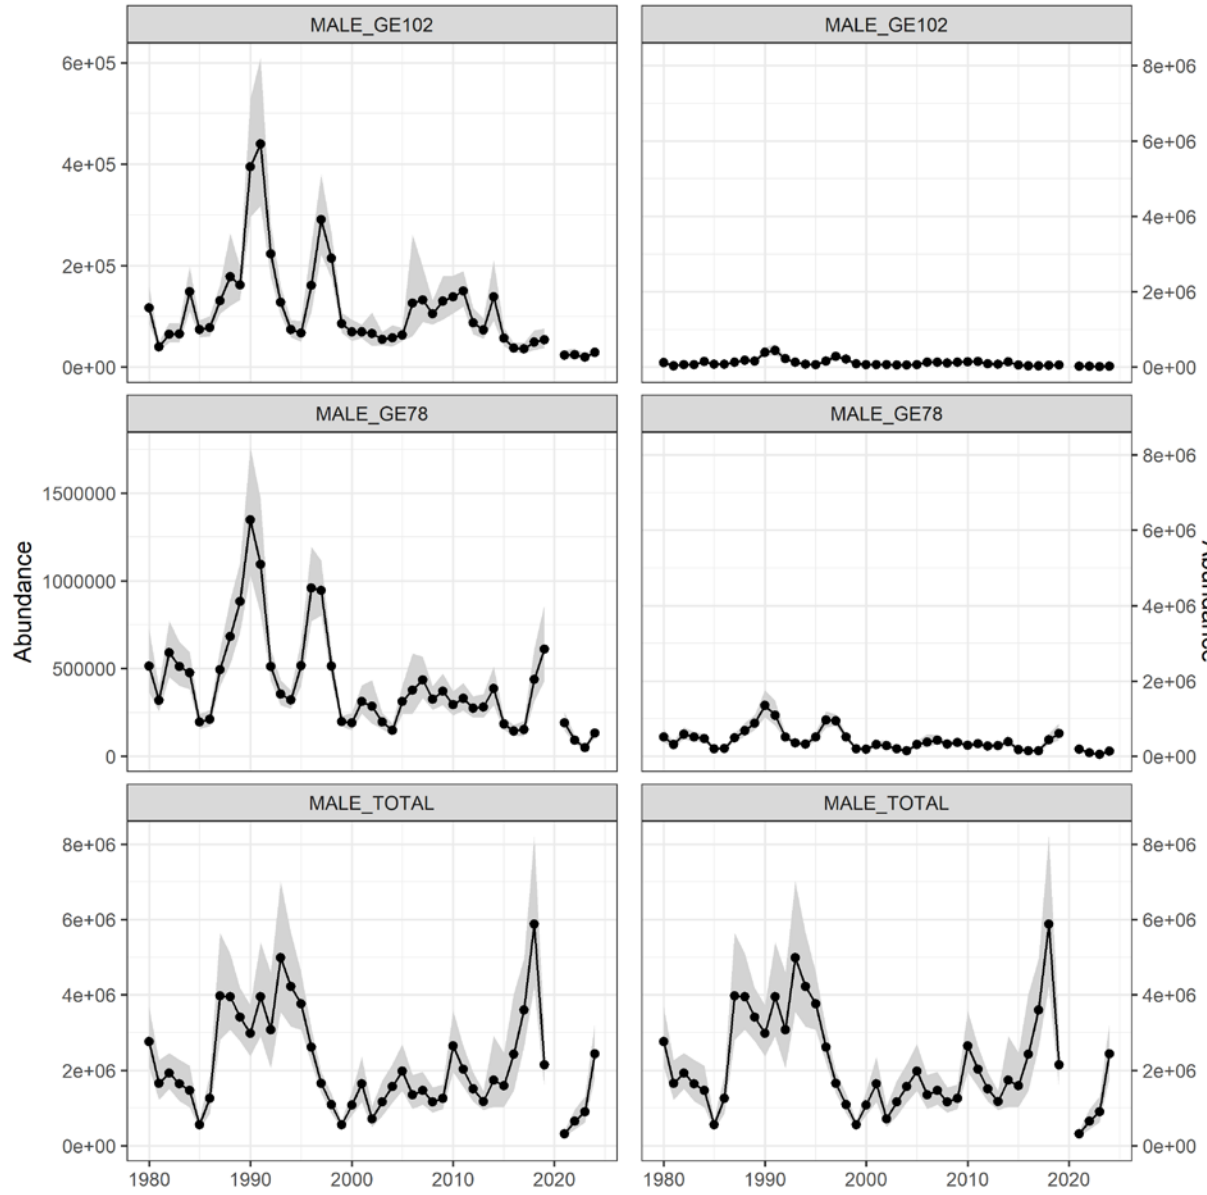

OPTIMISM

Females were doing fine

More immature females in the survey than ever in 2024

Recent record recruitments

Divergent trends for total and large males

CAUTION

Long slow decline for lg males

Steady decline in fishery CPUE since rationalization

Density dependence in maturity?

Final thoughts

- Stock is in bad shape with potential reasons for optimism
- Assessment model represents the biology better than ever
- Models are the only tools we have to:
 - try to understand the drivers of the stocks (e.g. why did the stock collapse?),
 - ask hypotheticals (e.g. what if we change selectivity?),
 - incorporate multiple data sources (e.g. BSFRF data)
- Management options were not designed with snow crab biology in mind
- Uncertainties around biology compound problems selecting reference points
- Harmonizing state and federal rules would be useful

Risk table

TOPIC	COMMENT	SCORE
Assessment	Biology good Reference points bad Fits to large males bad Jittering bad	Increased concern (2)
Population dynamics	Large males downward trajectory Recent population collapse Potential for density dependence in terminal molt	Extreme concern (3)
Environmental/ecosystem	ESP indicators mostly neutral	Normal (1)
Fishery performance	CPUE on a long-term downward trend since rationalization Fishery closure	Extreme concern (3)

Recommendations

- Reference points
 - Status quo tier 3 reference points allow for total removal of large males
 - Modified tier 3 reference points would have closed the fishery from 2014-present
 - **Tier 4 recommended**
- GMACS vs. survey
 - No immediate way to actually apply the exploitation rate associated with M given the estimated fishery selectivity
 - GMACS underestimates the large males considerably
 - Jittering issues also present with GMACS
 - **Use the survey estimates of males >101mm**
