# 2023 Stock Assessment and Fishery Evaluation Report for the Pribilof Islands Blue King Crab Fisheries of the Bering Sea and Aleutian Islands Regions 

William T. Stockhausen

2023-09-18

## THIS INFORMATION IS DISTRIBUTED SOLELY FOR THE PURPOSE OF

 PREDISSEMINATION PEER REVIEW UNDER APPLICABLE INFORMATION QUALITYGUIDELINES. IT HAS NOT BEEN FORMALLY DISSEMINATED BY NOAA
FISHERIES/ALASKA FISHERIES SCIENCE CENTER AND SHOULD NOT BE
CONSTRUED TO REPRESENT ANY AGENCY DETERMINATION OR POLICY

## 1 Executive Summary

### 1.1 Stock

Pribilof Islands blue king crab (PIBKC), Paralithodes platypus.

### 1.2 Catches

Retained catches have not occurred since 1998/99. Bycatch has been limited in recent years. Bycatch mortality in the crab (e.g., Tanner crab, snow crab) fisheries that incidentally take PIBKC was 0 t in 2022/23; the average discard mortality over the past five years in these fisheries was 0.004 t . Most bycatch mortality for PIBKC occurs in the BSAI groundfish fixed gear (pot and hook-and-line) fisheries (5-year average: 0.012 t ) and trawl fisheries ( 5 -year average: 0.218 t ). In $2022 / 23$, the estimated PIBKC bycatch mortality was 0.042 t in the groundfish fixed gear fisheries and 0.213 t in the groundfish trawl fisheries. Total fishing mortality in $2022 / 23$ was 0.255 t , while the 5 -year average was 0.234 t .

### 1.3 Stock biomass

Based on 5-year running average results from the NMFS EBS Shelf Survey (the time series for PIBKC starts in 1975), estimates of stock biomass were largest in the late 1970s ( $73,430 \mathrm{t}$ ), decreased by an order of magnitude by 2000 (to $3,936 \mathrm{t}$ ), and decreased by another order of magnitude by

2015 ( 577.0 t ). Average biomass over the last five years is 453.9 t . Biomass continues to fluctuate at low abundances in all size classes; any short-term trends are questionable because the survey estimates exhibit large uncertainties due to the patchiness of catches. 2023 was the first year in which the NMFS EBS bottom trawl survey failed to catch any mature male crab within the Pribilof Islands stock area.

### 1.4 Recruitment

Recruitment indices (e.g., immature males $<120 \mathrm{~mm}$ CL) from the EBS trawl survey are not well understood for PIBKC. Juveniles may not be well-assessed by the survey due to their use of untrawlable habitat, but abundance in the survey has remained consistently low over at least the past 10 years. Immature females have not been caught in the survey since 2018. Two immature males were caught in 2023, but none in 2022.

### 1.5 Management performance

Management quantities related to stock biomass for PIBKC, $B$ and $B_{M S Y}$, are based on mature male biomass-at-mating (MMB-at-mating). The Minimum Stock Size Threshold (MSST) is defined as $\frac{1}{2} B_{M S Y}$ : if current $B$ is above the MSST, the stock is not overfished. Management quantities related to fishing mortality are based on total catch (retained + discards) mortality. If total catch mortality is less than the overfishing limit (OFL), then overfishing is not occurring. As summarized in Tables A and B, current $B(180.4 \mathrm{t})$ is below the MSST determined in this assessment $(2,098 \mathrm{t})$ and consequently the stock is overfished. Total catch mortality in $2022 / 23$ ( 0.255 t ) was less than the OFL (1.160 t) so overfishing did not occur in 2022/23.

Table A. Management performance (in metric tons).

| Year | MSST | Biomass | TAC | Retained Catch | Total Catch Mortality | OFL | ABC |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $2020 / 21$ | 2,049 | 181 | closed | 0 | 0 | 1.16 | 0.87 |
| $2021 / 22$ | 2,098 | 235 | closed | 0 | 0.102 | 1.16 | 0.87 |
| $2022 / 23$ | 2,098 | 180 | closed | 0 | 0.25 | 1.16 | 0.87 |
| $2023 / 24$ | - | 181 | closed | - | - | 1.16 | 0.87 |
| $2024 / 25$ | - | 181 | closed | - | - | 1.16 | 0.87 |

Table B. Management performance (in millions of pounds).

| Year | MSST | Biomass | TAC | Retained Catch | Total Catch Mortality | OFL | ABC |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $2020 / 21$ | 4.517 | 0.399 | closed | 0 | 0 | 0.0026 | 0.0019 |
| $2021 / 22$ | 4.6250 | 0.5176 | closed | 0 | 0.0002 | 0.0026 | 0.0019 |
| $2022 / 23$ | 4.6250 | 0.3978 | closed | 0 | 0.000562 | 0.0026 | 0.0019 |
| $2023 / 24$ | - | 0.3980 | closed | - | - | 0.0026 | 0.0019 |
| $2024 / 25$ | - | 0.3980 | closed | - | - | 0.0026 | 0.0019 |

Notes: Based on data available to the Crab Plan Team at the time of the assessment for the crab fishing year.

### 1.6 Basis for the 2023/24 OFL

The value of $B_{M S Y}$ used to determine stock status is based on Tier 4 considerations. Here, the average estimated MMB-at-mating over the disjoint time period [1980/81-1984/85, 1990/91-1997/98] is used as a proxy for $B_{M S Y}$. The annual MMB-at-mating time series is estimated using a random walk model to reduce the inter-annual variability and large uncertainties associated with designbased estimates of MMB at the time of the survey. Subsequently, the model-estimated time series is projected forward to the time at which mating occurs (Feb. 15, by convention) while taking into account intervening natural and fishing mortality. Using this approach, the $B_{M S Y}$ proxy was determined to be $4,196 \mathrm{t}$. The estimated current MMB-at-mating is 180.4 t . The ratio of current MMB-at-mating to $B_{M S Y}$ is less than the value of the $F_{O F L}$ Control Rule parameter $\beta$ (0.25), so directed fishing is not allowed. The MMB-at-mating for $2023 / 24$ is 180.5 t , projected from the random walk model estimate of 2023 survey MMB to the time of mating (Feb. 15, 2024) based on natural mortality, assumptions regarding discard mortality in $2023 / 24$, and the $F_{\text {OFL }}$ control rule.

As per the rebuilding plan (Foy et al. 2014), the OFL is based on a Tier 5 calculation of average bycatch mortalities between 1999/2000 and 2005/06, which is a time period thought to adequately reflect the conservation needs associated with this stock and to acknowledge existing non-directed catch mortality. Using this approach, the OFL was determined to be 1.160 t for 2023/24.

Table C. Basis for the OFL (in metric tons).

| Year | Tier | $B_{M S Y}$ | $B$ | $B / B_{M S Y}$ | $\gamma$ | Years to define $B_{M S Y}$ | M | P* |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $2019 / 20$ | 4 c | 4,099 | 180 | 0.044 | 1 | $1980 / 81-1984 / 85 ; 1990 / 91-1997 / 98$ | 0.18 | $25 \%$ buffer |
| $2020 / 21$ | 4 c | 4,099 | 181 | 0.044 | 1 | $1980 / 81-1984 / 85 ; 1990 / 91-1997 / 98$ | 0.18 | $25 \%$ buffer |
| $2021 / 22$ | 4 c | 4,099 | 180 | 0.044 | 1 | $1980 / 81-1984 / 85 ; 1990 / 91-1997 / 98$ | 0.18 | $25 \%$ buffer |
| $2022 / 23$ | 4 c | 4,099 | 180 | 0.044 | 1 | $1980 / 81-1984 / 85 ; 1990 / 91-1997 / 98$ | 0.18 | $25 \%$ buffer |
| $2023 / 24$ | 4 c | 4,196 | 181 | 0.043 | 1 | $1980 / 81-1984 / 85 ; 1990 / 91-1997 / 98$ | 0.18 | $25 \%$ buffer |

Table D. Basis for the OFL (in millions of pounds).

| Year | Tier | $B_{M S Y}$ | $B$ | $B / B_{M S Y}$ | $\gamma$ | Years to define $B_{M S Y}$ | M | $\mathrm{P}^{*}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

| $2023 / 24$ | 4 c | 9.2500 | 0.3980 | 0.043 | 1 | $1980 / 81-1984 / 85 ; 1990 / 91-1997 / 98$ | 0.18 | $25 \%$ buffer |

### 1.7 Probability density function for the OFL

Not applicable for this stock.

### 1.8 ABC

The ABC was calculated using a $25 \%$ buffer on the OFL, as in assessments since 2015 (Stockhausen 2015). Thus, the ABC is $0.870 \mathrm{t}(=0.75 \times 1.160 \mathrm{t})$.

### 1.9 Rebuilding analyses results summary

The stock has been declared as overfished since 2002; a rebuilding plan was implemented in 2004 and revised in 2014. The revised rebuilding plan does not have a target rebuild date and NMFS cannot predict when, or if, rebuilding will occur. The 2023/24 stock assessment shows this stock is still overfished. The causes of the continued low abundance and failure to recover are not well-understood, but are thought to be predominantly due to environmental changes that inhibit recruitment. In April 2022, the Regional Administrator made the determination that PIBKC is "not making inadequate progress" towards rebuilding.

## 2 Summary of Major Changes

### 2.1 Management

In 2002, NMFS notified the NPFMC that the PIBKC stock was overfished. A rebuilding plan was implemented in 2003 that included the closure of the stock to directed fishing until the stock was rebuilt. In 2009, NMFS determined that the PIBKC stock was not rebuilding in a timely manner and would not meet the rebuilding horizon of 2014. Subsequently, Amendment 43 to the Crab FMP and Amendment 103 to the BSAI Groundfish FMP to rebuild the PIBKC stock were adopted by the Council in 2012 and approved by the Secretary of Commerce in early 2015 (NPFMC 2021). Amendment 103 closed the Pribilof Islands Habitat Conservation Zone (PIHCZ) to pot fishing for Pacific cod to promote bycatch reduction on PIBKC. Amendment 43 amended the prior rebuilding plan to incorporate new information on the likely rebuilding timeframe for the stock, taking into account environmental conditions and the status and population biology of the stock. No pot fishing for Pacific cod has occurred within the PIHCZ since 2015/16.

Full assessments for the PIBKC are conducted on a biennial (odd years) basis. The 2021 assessment (Stockhausen 2021) was conducted in May, prior to the 2021 NMFS EBS shelf survey and the completion of the crab year (July 1-June 30). The timing of the assessment was subsequently changed to September in order to be able to incorporate the current year's EBS shelf survey and bycatch data for the complete crab year.

### 2.2 2. Input data

Retained and discard catch time series were updated with data from the crab and groundfish fisheries for 2020/21-2022/23. Abundance and biomass data for PIBKC were added for the 20212023 NMFS EBS Shelf Bottom Trawl Surveys.

### 2.3 3. Assessment methodology

In 2017, PIBKC moved to a triennial schedule for full assessments following stock prioritization (Stockhausen 2017). In 2018, a partial assessment was conducted in 2018 (Stockhausen 2018) to determine whether overfishing occurred in the previous year. However, the NMFS Alaska Regional Office (AKRO) noted a biennial requirement to review the rebuilding status for PIBKC and that the assessment and rebuilding review should occur on the same schedule. Consequently, the 2019 and 2021 assessments were full assessments (Stockhausen 2019, 2021). However, the timing for the 2021 full assessment was changed from September to May. This change required the use of several estimates for quantities used in the assessment model, including survey MMB in the year of the assessment as well as retained catch and bycatch quantities in the fishery year prior to the assessment. The NMFS EBS Shelf Survey is typically conducted on annually in June-August, so biomass estimates from the survey in the year of the assessment were not available for the 2021 assessment, and a value projected by the random walk model used to estimate the survey MMB time series was used as a substitute to calculate MMB-at-mating for the 2021 assessment year. The directed fishery was closed in 2021/22, so there was no retained catch or bycatch associated with it. However, the Tanner crab (Chionoecetes bairdi), snow crab (C. opilio), and groundfish fisheries were still being prosecuted at the time the 2021 assessment was conducted, necessitating the use of estimates for the bycatch in these fisheries. To avoid these complications in the future, the assessment was moved to September for the 2023 assessment.

The methodology this year is the same as in the 2021 assessment, although the modeling used to estimate the random walk model for survey MMB was changed from a bespoke ADMB model to the R software rema package (R Core Team 2022; Sullivan 2022), which uses TMB (Kristensen et al. 2016) for optimizing model fit to the data. The Tier 4 approach used in this assessment for status determination is identical to that adopted by the CPT and SSC in 2015 and used in subsequent assessments (Stockhausen 2015, 2016, 2017, 2019, 2021).

### 2.4 4. Assessment results

Overfishing did not occur in 2022/23. $B_{M S Y}$ increased to $4,196 \mathrm{t}$ from the previous assessment ( $4,099 \mathrm{t}$ ) while the projected MMB-at-mating for 2023/24 ( 180.5 t ) remained similar to the previous assessment ( 180.4 t ). Stock status did not change: the stock remains in Tier 4c. The stock remains overfished and a directed fishery is prohibited in 2023/24. The recommended OFL (based on average catch), the ABC buffer, and the ABC are identical to last year's values ( $1.160 \mathrm{t}, 0.25$, and 0.870 t , respectively).

## 3 Responses to SSC and CPT Comments

### 3.1 Remarks pertinent to this assessment

### 3.1.1 CPT comments May 2023:

## CPT comment

The CPT agreed (following the author's recommendation) with the change to use the rema R package for the assessment.

## Author response

The rema R package, which underwent a favorable Center for Independent Experts (CIE) review during 2023, has been used to fit the random walk model to design-based estimates of MMB at the time of the survey.

### 3.1.2 SSC comments June 2023:

## SSC Comment

The SSC concurs with the author and CPT recommended application of the rema R package for this Tier 4 assessment.

## Author response

See Section 3.1.1.

## SSC Comment

The SSC also looks forward to the SAFE section on rebuilding in September as the rebuilding plan nears its second decade.

## Author response

The revised (2014) rebuilding plan does not have a target rebuild date and NMFS cannot predict when or if rebuilding will occur (NPFMC 2021). There is no new and unexpected information that would significantly alter the rebuilding expectations. The recent trajectory of the time series of MMB-at-survey time provides no evidence of an increasing trend. Further, survey size compositions provide no evidence for recent recruitment to the stock. The failure of the EBS shelf survey to catch any mature males this year does not raise the level of concern for this stock above what it has been in the recent past; the survey does not target blue king crab and the result is consistent with sampling a population at low (but non-zero) abundance. The causes of the continued low abundance and failure to recover are not well understood, but are thought to be predominantly due to environmental changes that inhibit recruitment. In April 2022, the last time a determination of overfished status was made was made, the Regional Administrator determined that PIBKC was "not making inadequate progress" towards rebuilding.

### 3.1.3 CPT comments September 2022:

None

### 3.1.4 SSC comments October 2022:

None

### 3.1.5 CPT comments May 2022:

None

### 3.1.6 SSC comments June 2022:

## None

### 3.1.7 CPT comments September 2021:

## None

### 3.1.8 SSC comments October 2021:

## None

### 3.1.9 CPT comments May 2021:

## CPT Comment

The CPT discussed the SAFE stock specification table with respect to PIBKC being a biennial assessment and whether the assessment should be brought back to a September CPT meeting cycle in order to fully account for any bycatch that occurs through the end of June. The advantages of an assessment review in September are that the most recent survey and bycatch data through the end of the June fishing year would be available, and there would be no need to revise the assessment with the final catches. The disadvantage is that it would add incrementally to the September workload, both for the assessment author and CPT. It was noted that the September workload has been reduced during odd years by shifting the SMBKC assessment to a biennial cycle. Therefore the CPT recommends that future PIBKC assessments (starting in 2023) should be conducted for September meetings.

## Author response

As recommended, this assessment was moved to September 2023.

## CPT Comment

The CPT recommends exploring VAST for the PIBKC assessment.

## Author response

As the CPT itself noted, "using VAST may be problematic when very small numbers of animals are caught at only a handful of stations (as with PIBKC)" and "biomass estimates from VAST may not be reliable, and estimated confidence intervals may be even less so". Consequently, this request was given a low priority (potential VAST applications in the Tanner crab assessment were addressed instead) and has not yet been addressed.

## CPT Comment

The CPT recommends "...exploring smoothing the survey point-estimate CVs (e.g., apply median CV for all years)".

## Author response

The random walk model implemented using the rema R package incorporates the annual variability in survey point estimates in a statistically-appropriate manner. Consequently, this recommendation has not been addressed.

### 3.1.10 SSC comments June 2021:

## SSC comment (general)

Crab assessments should generally follow the default groundfish practice of projecting the current year's catches if one or more fisheries are incomplete at the time of the assessment.

## Author response

Now that the PIBKC assessment is again conducted for September/October, this is no longer an issue for this assessment.

## SSC Comment

The SSC supports the CPT recommendation to move the timing of the PIBKC assessment back to September for the CPT.

## Author response

As recommended, this assessment was conducted for the September 2023 meeting.

## SSC comment

The SSC looks forward to the report on the blue king crab stock structure template in the near future.

## Author response

Staff capacity has not permitted progress on this request.

## 4 Introduction

### 4.1 Stock

Pribilof Islands blue king crab (PIBKC), Paralithodes platypus.

### 4.2 Distribution

Blue king crab are anomurans in the family Lithodidae, which also includes the red king crab (Paralithodes camtschaticus) and golden or brown king crab (Lithodes aequispinus) in Alaska. Blue king crab are found in widely-separated populations across the North Pacific (Figure 1). In the western Pacific, blue king crab occur off Hokkaido in Japan and isolated populations have been observed in the Sea of Okhotsk and along the Siberian coast to the Bering Straits. In North America, they are found in the Diomede Islands, Point Hope, outer Kotzebue Sound, King Island, and the outer parts of Norton Sound. In the remainder of the Bering Sea, they are found in the waters off St. Matthew Island and the Pribilof Islands. In more southerly areas, blue king crab are found in the Gulf of Alaska in widely-separated populations that are frequently associated with fjord-like bays (Figure 1). The insular distribution of blue king crab relative to the similar but more broadly distributed red king crab is likely the result of post-glacial-period increases in water temperature that have limited the distribution of this cold-water adapted species (Somerton 1985). Factors that may be directly responsible for limiting the distribution include the physiological requirements for reproduction, competition with the more warm-water adapted red king crab, exclusion by warmwater predators, or habitat requirements for settlement of larvae (Armstrong et al. 1985, 1987; Somerton 1985).

### 4.3 Stock structure

The stock structure of blue king crab in the North Pacific is largely unknown. Stoutamore (2014) found significant genetic divergence between all sites comparing genetic samples collected from sites in Southeast Alaska, the Pribilof Islands, St. Matthew Island, Little Diomede, Chaunskaya Bay, Shelikhov Gulf, and the western Bering Sea, with Southeast Alaska exhibiting the highest divergence from the other sites. Allele frequencies from the Pribilofs and St. Matthew (and Little Diomede) grouped together more closely than with other sites based on Principal Components Analysis. Temporal changes were significant between samples collected in the Pribilofs and at St. Matthew in the early 1990s and ones collected during 2006-2011, although there was no evidence these changes were due to recent population bottlenecks. Stoutamore (2014) suggested that this apparent genetic drift could be a consequence of the large decreases in abundance at these locations since the early 1980s.

The potential for species interactions between blue king crab and red king crab as a cause for PIBKC shifts in abundance and distribution was addressed in a previous assessment (Foy 2013). Foy (2013) compared the spatial extent of both species in the Pribilof Islands from 1975 to 2009
and found that, in the early 1980's when red king crab first became abundant, blue king crab males and females dominated the stations (numbering between 1 and 7 ) where the species co-occurred in the Pribilof Islands District. Spatially, the stations with co-occurrence were broadly distributed around the Pribilof Islands. In the 1990's, the red king crab population increased substantially as the blue king crab population decreased. During this time period, the number of stations with co-occurrence remained around a maximum of 8 , but they were equally dominated by both blue king crab and red king crab-suggesting a direct overlap in distribution at the scale of a survey station. During this time period, the stations dominated by red king crab were dispersed around the Pribilof Islands. Between 2001 and 2009 the blue king crab population decreased dramatically while the red king crab population fluctuated. The number of stations dominated by blue king crab in 2001-2009 was similar to that for stations dominated by red king crab for both males and females, suggesting continued competition for similar habitat. The only stations dominated by blue king crab in the latter period were to the north and east of St. Paul Island. Although blue king crab protection measures also afford protection for the red king crab in this region, red king crab stocks continue to fluctuate (more so than simply accounted for by the uncertainty in the survey).

During the years when the fishery was active (1973-1989, 1995-1999), PIBKC were managed by the Alaska Department of Fish and Game (ADF\&G) under the Bering Sea king crab Registration Area Q Pribilof District ((Bowers et al. 2008); Figure 2). In the Pribilof District, blue king crab occupy the waters adjacent to and northeast of the Pribilof Islands (Armstrong et al. 1987). For assessment purposes, the Pribilof District as shown in Figure 2, with the addition of a 20 nm mile strip to the east of the District (bounded by the dotted red line in Figure 2), is considered to define the stock boundary for PIBKC.

### 4.4 Life History

Blue king crab are similar in size and appearance, except for color, to the more widespread red king crab, but are typically biennial spawners with lesser fecundity and somewhat larger sized (ca. 1.2 mm ) eggs (Somerton and MacIntosh 1983; Jensen et al. 1985; Somerton and MacIntosh 1985; Jensen and Armstrong 1989; Selin and Fedotov 1996). Blue king crab fecundity increases with size, from approximately 100,000 embryos for a $100-110 \mathrm{~mm}$ carapace length (CL) female to approximately 200,000 for a female $>140-\mathrm{mm}$ CL (Somerton and MacIntosh 1985). Blue king crab have a biennial ovarian cycle with embryos developing over a 12- or 13-month period depending on whether or not the female is primiparous or multiparous, respectively (Stevens 2006a). Armstrong et al. (1985) and Armstrong et al. (1987), however, estimated the embryonic period for Pribilof blue king crab at 11-12 months, regardless of previous reproductive history. Somerton and MacIntosh (1985) placed development at 14-15 months. It may not be possible for large female blue king crab to support the energy requirements for annual ovary development, growth, and egg extrusion due to limitations imposed by their habitat, such as poor quality or low abundance of food or reduced feeding activity due to cold water (Armstrong et al. 1987; Jensen and Armstrong 1989). Both the large size reached by Pribilof Islands blue king crab and the generally high productivity of the Pribilof area, however, argue against such environmental constraints. Stoutamore (2014) found no genetic evidence to support a hypothesis for two genetically-distinct strains extruding and hatching eggs on alternate years. Development of the fertilized embryos occurs in the egg cases attached to the pleopods beneath the abdomen of the female crab and hatching occurs February through April (Stevens 2006b). After larvae are released, large female Pribilof blue king crab will molt, mate,
and extrude their clutches the following year in late March through mid-April (Armstrong et al. 1987). Stoutamore (2014) found strong genetic evidence for a single-paternity mating system.

Female crab require an average of 29 days to release larvae, and release an average of 110,033 larvae (Stevens 2006b). Larvae are pelagic and pass through four zoeal larval stages that last about 10 days each, with length of time being dependent on temperature: the colder the temperature the slower the development and vice versa (Stevens et al. 2008). Stage I zoeae must find food within 60 hours as starvation reduces their ability to capture prey (Paul and Paul 1980) and successfully molt. Zoeae consume phytoplankton, the diatom Thalassiosira spp. in particular, and zooplankton. The fifth larval stage is the non-feeding (Stevens et al. 2008) and transitional glaucothoe stage in which the larvae take on the shape of a small benthic crab but retain the ability to swim by using their extended abdomen as a tail. This is the stage at which the larvae search for appropriate settling substrate and, upon finding it, molts to the first juvenile stage and henceforth remains benthic. The larval stage is estimated to last for 2.5 to 4 months and larvae metamorphose and settle during July through early September (Armstrong et al. 1987; Stevens et al. 2008).

Blue king crab molt frequently as juveniles, growing a few mm in size with each molt. Unlike red king crab juveniles, blue king crab juveniles are not known to form pods. Female king crab typically reach sexual maturity at approximately five years of age, while males may reach maturity at six years of age (NPFMC 2003). Female size at $50 \%$ maturity for Pribilof blue king crab is estimated to be $96-\mathrm{mm}$ CL and size at maturity for males, estimated from chela height relative to carapace length, is estimated to be $108-\mathrm{mm}$ CL (Somerton and MacIntosh 1983). Skip molting occurs with increasing probability for males larger than 100 mm CL (NMFS 2005).

Longevity is unknown for this species due to the absence of hard parts retained through molts with which to age crabs. Estimates of 20 to 30 years in age have been suggested (Blau 1997). Natural mortality for male Pribilof blue king crab has been estimated at $0.34-0.94$ with a mean of 0.79 (Otto and Cummiskey 1990) and a range of 0.16 to 0.35 for Pribilof and St. Matthew Island stocks combined (Zheng et al. 1997). An annual natural mortality of $0.2 \mathrm{yr}^{-1}$ for all king crab species was originally adopted in the federal crab fishery management plan for the BSAI areas (Siddeek et al. 2002). This was subsequently revised and a rate of $0.18 \mathrm{yr}^{-1}$ is currently used for PIBKC.

### 4.5 Management history

The blue king crab stock in the Pribilof District is currently overfished and the directed fishery has been closed since 1999/2000 (Bowers et al. 2011; NPFMC 2014a; Stockhausen 2021). Bottom trawl gear and pot fishing for Pacific cod are currently excluded from the Pribilof Islands Habitat Conservation Zone (PIHCZ, Figure 3) to minimize bycatch of PIBKC in the groundfish fisheries. Fishing for Tanner crab and snow crab is also prohibited within annual area closures implemented by ADF\&G that generally incorporate the PIHCZ.

The blue king crab fishery in the Pribilof District began in 1973 with a reported catch of 580 t by eight vessels (Table 1; Figure 4). Landings increased during the 1970s and peaked at a harvest of $5,000 \mathrm{t}$ in the 1980/81 season (Table 1; Figure 4), with an associated increase in effort to 110 vessels (Bowers et al. 2008). The fishery occurred September through January, but usually lasted less than six weeks (Otto and Cummiskey 1990; Bowers et al. 2008). The fishery was male only, and legal size was $>165-\mathrm{mm}$ carapace width (NPFMC 1994). Guideline harvest levels (GHL) were 10 percent of the estimated abundance of mature males or 20 percent of the estimated number of legal males (Bowers et al. 2008).

Pribilof Islands blue king crab occasionally occur as bycatch in the eastern Bering Sea snow crab fishery, the western Bering Sea Tanner crab fishery, the Bering Sea hair crab (Erimacrus isenbeckii) fishery, and the Pribilof red and blue king crab fisheries. In addition, blue king crab are taken as bycatch in groundfish fisheries by both fixed and trawl gear, primarily those targeting Pacific cod, flathead sole and yellowfin sole (Tables 3-6).

Amendment 21a to the BSAI Groundfish FMP prohibited the use of non-pelagic trawl gear in the Pribilof Islands Habitat Conservation Area (subsequently renamed the Pribilof Islands Habitat Conservation Zone in Amendment 43; Figure 3), which the amendment also established (NPFMC 1994). The amendment went into effect January 20, 1995 and protects the majority of crab habitat in the Pribilof Islands area from the impact of bottom contact trawl gear.

Declines in the PIBKC stock after 1995 resulted in a closure of directed fishing from 1999 to the present. The stock was declared overfished in September 2002, and ADF\&G developed a rebuilding harvest strategy as part of the NPFMC comprehensive rebuilding plan for the stock. The rebuilding plan also included the closure of the stock to directed fishing until it was rebuilt. In 2009, NMFS determined that the PIBKC stock was not rebuilding in a timely manner and would not meet the rebuilding horizon of 2014. Subsequently, Amendment 43 to the King and Tanner Crab Fishery Management Plan (FMP) and Amendment 103 to the BSAI Groundfish FMP to rebuild the PIBKC stock were adopted by the Council in 2012 and approved by the Secretary of Commerce in early 2015. Amendment 103 closes the Pribilof Islands Habitat Conservation Zone (Figure 3) to pot fishing for Pacific cod to promote bycatch reduction on PIBKC. Amendment 43 amends the prior rebuilding plan to incorporate new information on the likely rebuilding time frame for the stock ( $>$ 50 years), considering environmental conditions and the status and population biology of the stock (NPFMC 2014a).

## 5 Data

### 5.1 Summary of new information

The time series of retained and discarded catch in the crab fisheries was updated for 2020/212022/23 from ADF\&G data (B. Daly, ADF\&G, pers. comm.): there was no retained catch and no observed (and thus no expanded) bycatch in any of these years. Similarly, the time series of PIBKC bycatch in the groundfish fisheries was updated for the past three fishing years using data served by AKFIN from the AKRO's Catch-in-Areas database: total (expanded) bycatch was 0.007 t and total mortality was 0.001 t in $2020 / 21,0.139 \mathrm{t}$ and 0.093 t in $2021 / 22$, and 0.476 t and 0.255 t in 2022/23, respectively.

The survey MMB time series and related data for PIBKC were updated with results from the 2021-2023 NMFS EBS shelf bottom trawl surveys. Design-based estimates of survey MMB were 0.405 t in 2021, 0.112 t in 2022, and 0 t in 2023 . The corresponding numbers of mature males caught in the survey were 9,2 , and 0 .

### 5.2 Crab fisheries

### 5.2.1 Retained catch

The directed fishery has been closed since 1999/2000. Historical retained catch data (Table 1, Figure 4) were obtained from Bowers et al. (2011). Retained catch data start in 1973, reaching a maximum of 4,976 tin 1980/1981 before dropping precipitously. In the 1995/96 to 1998/99 seasons, blue king crab and red king crab were fished under the same Guideline Harvest Level (GHL). Total allowable catch (TAC) for the directed fishery has been set at zero since 1999/2000; there will be no retained catch allowed during the 2023/24 crab fishing season.

### 5.2.2 Bycatch and discard mortality

Estimates for annual bycatch of PIBKC in the crab fisheries is provided by ADF\&G for sublegal males ( $<138 \mathrm{~mm}$ CL), legal males ( $\geq 138 \mathrm{~mm} \mathrm{CL}$ ), and females based on data collected by onboard observers in the snow crab and Tanner crab fisheries (aggregated across fisheries in Table 2 and Figure 4), although data may be incomplete for some of these fisheries. Prior to 1998/99, observer data exist only for catcher-processor vessels, so discarded catch before this date are not included here. Catch weight was calculated by first determining the mean weight for crabs in the three categories (legal non-retained, sublegal, and female). The average weight for each category was then calculated from length frequency tables, where the carapace length ( $z$, in mm ) was converted to weight ( $w$, in g ) using the following equation:

$$
\begin{equation*}
w=\alpha \cdot z^{\beta} \tag{1}
\end{equation*}
$$

Values for the length-to-weight conversion parameters $\alpha$ and $\beta$ were applied across the time period (males: $\alpha=0.000508, \beta=3.106409$; females: $\alpha=0.02065, \beta=2.27$; Daly et al. (2014)). Average weights $(\bar{W})$ for each category were calculated using the following equation:

$$
\begin{equation*}
\bar{W}=\frac{\sum w_{z} \cdot n_{z}}{\sum n_{z}} \tag{2}
\end{equation*}
$$

where $w_{z}$ is crab weight-at-size $z$ (i.e., carapace length) using Equation 1, and $n_{z}$ is the number of crabs observed at that size in the category. Finally, estimated total non-retained weights for each crab fishery were the product of average weight $(\bar{W})$, CPUE (numbers/observed pot) based on observer data, and total effort (pot lifts) in each crab fishery.

As in the previous assessment (Stockhausen 2021), a $20 \%$ handling mortality rate was applied to the bycatch estimates to calculate discard mortality on PIBKC in these pot fisheries. In assessments prior to 2017, a handling mortality rate of $50 \%$ was applied to bycatch in the pot fisheries. The revised value used here is now consistent with the rates used in other king crab assessments (e.g., Zheng 2016). Estimates of bycatch and discard mortality (Table 2 and Figure 4) reached a maximum of 1.950 t for discard mortality by 1999/00, after which they decline to near zero, with an average over the last five years for discard mortality of only 0.004 t .

For 2022/23, discard mortality in the crab fisheries was 0 t (Ben Daly, ADF\&G, pers. comm. July 6,2023 ).

### 5.3 Bycatch in the groundfish fisheries

Bycatch estimates of PIBKC in the groundfish fisheries are based on groundfish observer data sampling expanded to total catch. Historical estimates beginning in 1996 are available to 2009 from AKFIN using results from the old Catch Accounting System database. This data is limited in its spatial resolution to NMFS statistical areas, which do not conform to the PIBKC stock area. As with previous assessments, estimates of blue king crab bycatch in the groundfish fisheries from NMFS statistical area 513 are assumed to account for bycatch within the PIBKC stock area. More recent estimates, 2008-present, are available from AKFIN using results from the AKRO's Catch-In-Areas database, which provides standardized spatial resolution using ADF\&G statistical areas (among other improvements over the older Catch Accounting System). In 2019, the algorithm used by AKFIN to expand observer data was changed from one based on retained groundfish catch weight to the one currently used by AKRO, which is based on total groundfish catch weight. This was applied retroactively to data from calendar year 2017 forward, affecting estimates for crab starting in crab year 2016.

Here, bycatch in the groundfish fisheries during 1991/92-2022/23 is documented. The data were downloaded from AKFIN on July 20, 2023 for the current assessment. In order to apply gear-specific discard mortality rates to the bycatch data, trawl gear types (pelagic and non-pelagic) have been aggregated as "trawl" gear, while hook-and-line (longline) and pot gear have been aggregated as "fixed" gear. As in previous assessments, discard mortality rates of 0.2 and 0.8 have subsequently been applied by gear type (fixed and trawl, respectively) to the estimated bycatch biomass to estimate fishing-related mortality for the discarded crab (Stockhausen 2021). Since 2009/10, the maximum annual bycatch of PIBKC in the groundfish fisheries was 1.552 t in 2015/16, while the maximum total discard mortality was 0.795 t in 2015/16. In contrast, the average bycatch over the last 5 years is 0.166 t , while the average discard mortality is 0.115 t .

### 5.3.1 Bycatch by gear type

Annual estimates of bycatch abundance, biomass, and discard mortality of PIBKC in the groundfish fisheries are presented in Table 3 and Figures 5 and 6 by (aggregated) gear type. In general, trawl gear takes more PIBKC than fixed gear, and with higher mortality, although exceptions occur (e.g., 2011/12, 2013/14, and 2014/15). The average mortality on PIBKC taken by trawl gear over the last five years is 0.218 t while that taken by fixed gear is 0.012 t .

### 5.3.2 Bycatch by target type

Annual estimates of bycatch abundance, biomass, and discard mortality of PIBKC in the groundfish fisheries are presented by groundfish target type in Tables 4-6 and Figure 7. Groundfish targets with less than 10 kg bycatch over the 2009/10-2022/23 period have been dropped. PIBKC is primarily taken as bycatch in fisheries targeting flathead sole, yellowfin sole, northern rock sole, and Pacific cod. Although the Pacific cod fishery accounted for the highest bycatch of PIBKC (in 2015) across the time series, it generally ranks below the other fisheries as a source of mortality because the bycatch occurs primarily with fixed gear.

### 5.3.3 Spatial patterns of bycatch

Spatial patterns of PIBKC bycatch, by ADF\&G stat area, in the groundfish fisheries are illustrated by gear type in Figures 8 and 9. Bycatch taken with trawl gear tends to be concentrated along and to the northeast of the eastern boundary of the Habitat Conservation Zone (non-pelagic trawl gear is excluded from the Zone), although 2012 was an exception in which bycatch was concentrated along the western edge of the Zone. In contrast, bycatch taken by fixed gear is typically dispersed along the shelf edge, although it was concentrated within and near the Habitat Conservation Zone (Figure 3) in 2015/16.

### 5.4 Catch-at-length

No catch-at-length data is used in the assessment.

### 5.5 NMFS EBS bottom trawl shelf survey

Time series of annual estimates of area-swept abundance and biomass, as well as size composition data, are available for PIBKC from the summer NMFS EBS Shelf Bottom Trawl Survey based on the stock area first defined in the 2013 assessment (Foy 2013), which includes the Pribilof District and a 20 nm strip adjacent to the eastern edge of the District (Figure 2). The adjacent area was added as a result of the 2015 rebuilding plan and the concern that crab outside the Pribilof District were not being accounted for in the assessment. The survey has been conducted annually since 1975, with the exception of 2020 . In 2020, the survey was not conducted due to issues associated with the global COVID-19 pandemic.

The standardized EBS bottom trawl survey is based on a systematic design with a fixed sampling station at the center of each $37.04 \times 37.04 \mathrm{~km}(20 \times 20$ nautical mile) grid square (Lauth and Nichol 2013). In the area surrounding the Pribilof Islands, high-density "corner stations" are sampled to better assess local blue king crab concentrations (Figure 10). Since 1982, the survey has used standard 83-112 Eastern otter trawls, which have $25.3-\mathrm{m}$ ( 83 ft ) headropes and $34.1-\mathrm{m}$ (112 ft) footropes, to sample crab and groundfish species at 77 stations within the Pribilof District, augmented by a column of 9 stations to the east of the District (indicated by the dashed red line in Figure 2) to better encompass the stock limits. The standard tow is nominally 30 minutes on bottom at a tow speed of 3 knots ( $\sim 1.5 \mathrm{nmi}$ distance), but net mensuration gear is used to more accurately assess time and distance "on bottom" as well as net width to provide a precise estimate of area swept. The net mensuration gear also allows the collection of depth and temperature data. Details of the NMFS bottom trawl protocols established by the National Oceanic and Atmospheric Administration can be found in (Stauffer 2004).

For each tow, all crab were removed from the catch, sorted by species and sex, and a total catch weight was obtained for each species (e.g., Zacher et al. 2023). All blue king crab were sampled for biological characteristics, including sex, carapace length (to 0.1 mm ), weight, shell condition, and egg color, egg condition, and clutch size for females. Male crab were characterized as immature,
mature, sublegal, and legal based on the size categories in Table 7. Females were characterized as immature or mature based on abdominal flap morphology and egg presence (Zacher et al. 2023).

Biomass estimates were calculated using the number of individual male and female crab at each 1 mm size category, using weight-size relationships developed by the AFSC's Kodiak Laboratory (the same as those applied to fishery data: Equation 1; Zacher et al. (2023)). Weights were calculated for each 1 mm size bin and summed within the legal male, sublegal male, mature, and immature size categories for each sex caught at a station. Total biomass was estimated by averaging crab density (biomass /area swept) from all stations within the area-augmented Pribilof District, and multiplying by the total area (Zacher et al. 2023).

Forty-five stations were included in survey strata for PIBKC in 1975, increasing to 86 by 1983 and remaining essentially constant since then (Tables 8 and 9 ). In the early 1980s, males were found at up to 38 of these stations and females were found at up to 24 . This decreased in the 1990s when males occurred in a maximum of 22 stations, with females occurring at a maximum of 15 stations. Since 2010, the maximum number of stations at which males were caught is 9 , with a median of 5 , while females were caught at a maximum of 8 stations, with a median of 4 . In similar fashion, the number of males caught declined from a maximum of 858 in 1975 to a since-2010 maximum of 22 ; for females, the corresponding numbers are 343 (in 1981) and 24. In most years, more mature crab were caught than immature, although there were exceptions (e.g., 1989 for both sexes). In 2023, a total of 2 (immature/sublegal) males and 7 (mature) females were caught at 2 and 1 stations, respectively, all in the high-density sampling area (Tables 8 and 9 ). No mature males were caught in 2023.

Annual survey abundance and biomass for PIBKC have declined precipitously over the course of the 45 year time series (Tables 10-15 and Figures 11-22). On decadal scales, mean survey abundance and biomass have declined for males from 13.141 million crab and 29.53 thousand t in the 1970s to 0.224 million crab and 0.402 thousand t in the 2010s. Similarly, mean survey abundance and biomass have declined for females from 8.862 million crab and 8.078 thousand $t$ in the 1970 s to 0.255 million crab and 0.230 thousand t in the 2010s. Dampened oscillations in survey abundance and biomass have occurred on roughly decadal scales for this stock, with maxima exhibited at the start of the time series for males, followed by a decline to low values in the mid-to-late 1980s, an increase to a relative maximum in the early 1990s, followed by a decline to consistent low values since 1999 (a "blip" with large confidence intervals in 2005 was the exception). Females show a similar pattern, but lagged perhaps 5 years or so (without a "blip" in 2005). In 2019, apparent increases observed in mature and legal male biomass estimates relative to 2018 were attributed primarily to an abbreviated, but "still valid," tow that may have had the effect of artificially increasing the CPUE calculated for the affected station (Zacher et al. 2020).

One feature that characterizes survey-based estimates of abundance and biomass for PIBKC is the large uncertainty (cv on the order of $0.5-1$ ) associated with the estimates, which complicates the interpretation of sometimes large interannual swings in estimates of abundance (Tables 12 and 13, Figures 11-16) and biomass (Tables 14 and 15, Figures 17-22). Estimated total abundance of male PIBKC from the NMFS EBS bottom trawl survey declined from $\sim 24$ million crab in 1975, the first year of the "standardized" survey, to $\sim 150,000$ in 2016 (the lowest estimated abundance since 2004, which was the minimum for the time series. Following a general decline to a low-point in 1985 ( $\sim 500,000$ males), abundance increased by a factor of 10 in the early 1990s, then generally declined (with small-amplitude oscillations superimposed) to the present. Estimated female abundance
generally followed a similar trend, spiking at 180 million crab in 1980, from $\sim 13$ million crab in 1975 and only $\sim 1$ million in 1979, then returned to more typical levels in 1981 ( $\sim 6$ million crab). More recently, abundance has fluctuated around 200,000 females. Estimated biomass for both males and females has followed trends similar to those in abundance.

Size frequencies across the entire time series are shown by sex in Figures 23-25. Based on patterns for crab $>50 \mathrm{~mm}$ CL, a single recruitment event starting in 1988 is evident in Figure 24, with a second possible event starting in 2005. However, these plots provide little evidence of recent recruitment.

The small numbers of crab caught in recent surveys make it difficult to draw firm conclusions regarding spatial patterns (Figures 26-29). Examining decadaly-averaged patterns, however, there appears to have been a fairly strong contraction in range from extending beyond the PIHCZ in the 1980s to contained within the PIHCZ currently. The current spatial pattern of PIBKC abundance is centered fairly compactly within the Pribilof District to the east of St. Paul Island and north of St. George Island, within a 60 nm radius of St. Paul.

## 6 Analytic Approach

### 6.1 History of modeling approaches

A catch survey analysis was used to assess the stock in the past (Zheng et al. 1997), but it is no longer in use. In October 2013, the SSC concurred with the CPT that the PIBKC stock falls under Tier 4 for status determination (SSC 2013). Stock status is determined by comparing current $B$ to the Minimum Stock Size Threshold (MSST), where $B$ is current MMB at the time of mating (by convention, MMB on Feb 15) and the MSST is $\frac{1}{2} B_{M S Y}$. For a Tier 4 stock, it is not possible to determine $B_{M S Y}$ and MSST directly. Instead, time-averaged MMB-at-mating is used as a proxy for $B_{M S Y}$, where the averaging is over a time period assumed to be representative of the stock being fished at an average rate near $F_{M S Y}$ such that the stock is fluctuating around $B_{M S Y}$. However, MMB-at-mating is not directly observed. Instead, estimates of MMB at the time of the NMFS EBS Shelf Survey are combined with estimates of natural mortality $(M)$, retained catch mortality ( $R M$ ), and discard catch mortality of crab taken as bycatch in the directed fishery and other fisheries ( $D M$ ). The current modeling approach uses $M$ for king crab (0.18), and annual estimates of $R M$ and $D M$ to project design-based estimates of MMB at the time of the survey (July 1, by convention) forward to the time of mating.

The sampling-related uncertainty associated with annual design-based estimates of MMB from the survey is extremely large for PIBKC; thus, different approaches have been used to provide a "smoothed" version of MMB at the time of the survey from which to project forward to estimate MMB-at-mating. In the 2013 and 2014 assessments (Foy 2013; Stockhausen 2014), inverse-variance (IV) averaging was used to smooth the annual survey biomass estimates. In the 2015 assessment (Stockhausen 2015), an AD Model Builder (Fournier et al. 2016) state space/random effects random walk (SS/RE RW) model was developed to estimate annual survey MMB to use in estimating $B_{M S Y}$. One advantage of the SS/RE RW model over the IV approach is that it provided an estimate of
process error in the MMB time series. Other advantages included handling missing data and providing a method to project uncertainty. An updated version of the SS/RE RW model utilizing the rema R package (R Core Team 2022; Sullivan 2022) used in the Tier 5 groundfish assessments was reviewed and endorsed by the CPT and SSC during the May and June, 2023 meetings Plan Team) (2023). Thus, this assessment uses the rema SS/RE RW implementation, which reduces the observed variance in estimates of design-based annual survey MMB, estimates missing values (the survey was not conducted in 2020), and better characterizes the temporal trends in MMB at the time of the survey prior to calculating a MMB-at-mating time series.

Since 2017, PIBKC assessments have been conducted on an odd-year biennial schedule. The assessment timing was moved from September to May prior to the 2021 assessment, which required that several data inputs to the model (assessment year MMB at the time of the survey and retained catch and bycatch values from the crab fishery year prior to the assessment year) be estimated in some fashion. This proved to be unsatisfactory, resulting in the assessment timing moved back to September for this assessment, with the result that this 2023 assessment uses complete 2022/23 catch and survey data without any extrapolation.

### 6.2 Model Description

### 6.2.1 MMB at the time of the survey

Survey MMB in year $y, M M B_{y}^{s}$, is calculated from haul-level survey data by first calculating haul-level MMB, $M M B_{y, h}^{s}$, using:

$$
\begin{equation*}
M M B_{y, h}^{s}=\sum_{z} w_{z} \cdot P_{z} \cdot n_{y, h, z}^{s} \tag{3}
\end{equation*}
$$

where $w_{z}$ is male weight at size $z(\mathrm{~mm} \mathrm{CL}), P_{z}$ is the probability of maturity at size $z$, and $n_{y, h, z}^{s}$ is the number of males caught (expanded for sub-sampling) at size $z$ in survey haul $h$ in year $y$. For PIBKC, $P_{z}$ is a knife-edge function, with all males larger than 119 mm CL being mature (Table 7). Haul-level $M M B_{y, h}^{s}$ is then expanded to survey-level $M M B_{y}^{s}$ using standard design-based survey methods (Wakabayashi et al. 1985).

The SS/RE RW model is a statistical approach that models annual log-scale changes in "true" survey MMB as a random walk process using

$$
\begin{equation*}
p\left(<\ln \left(M M B_{y}^{s}\right)>\mid<\ln \left(M M B_{y-1}^{s}\right)>\right) \sim N\left(0, \phi^{2}\right) \tag{4}
\end{equation*}
$$

as the state equation, where $<\ln \left(M M B_{y}^{s}\right)>$ is the estimated "true" ln-scale survey MMB in year $y, p(x \mid \theta)$ denotes the probability of $x$ conditional on $\theta, N(\mu, v)$ indicates the normal distribution with mean $\mu$ and variance $v$, and $\phi^{2}$ represents the estimated (ln-scale) process error variance. The associated observation equation is

$$
\begin{equation*}
\ln \left(M M B_{y}^{s}\right)=<\ln \left(M M B_{y}^{s}\right)>+\eta_{y}, \text { where } \eta_{y} \sim N\left(0, \sigma_{y}^{s^{2}}\right) \tag{5}
\end{equation*}
$$

where $M M B_{y}^{s}$ is the design-based ("observed") survey MMB in year $y, \eta_{y}$ represents normallydistributed $\ln$-scale observation error, and $\sigma_{y}^{s^{2}}$ is the $\ln$-scale design-based survey MMB variance in year $y$. The $M M B_{y}^{s}$ 's and $\sigma_{y}^{s}$ 's are observed quantities, while the $<\ln \left(M M B_{s}\right)>$ 's are estimated parameters regarded as random effects in the likelihood function. The process error variance $\phi^{2}$ is parameterized on the $\ln$-scale using $\phi^{2}=\exp (2 \cdot \lambda)$, where $\lambda$ is an estimated fixed effect parameter.

Parameter estimates are obtained by minimizing the joint negative log-likelihood objective function

$$
\begin{equation*}
\Lambda=\sum_{y}\left[\ln (2 \pi \phi)+\left(\frac{<\ln \left(M M B_{y}^{s}\right)>-<\ln \left(M M B_{y-1}^{s}\right)>}{\phi}\right)^{2}\right]+\sum_{y}\left(\frac{\ln \left(M M B_{y}^{s}\right)-<\ln \left(M M B_{y}^{s}\right)>}{\sigma_{y}^{s}}\right)^{2} \tag{6}
\end{equation*}
$$

and integrating out the random effects using the Laplace approximation.
One drawback associated with the SS/RE RW model described here is that the observed survey MMB is fit on a natural log scale, which cannot accommodate zeros as observations (the natural log of zero is negative infinity). This has not been an issue for the PIBKC assessment in the past but, unfortunately, this situation needs to be addressed in this assessment (and in future assessments) because the design-based estimate of survey MMB for 2023 is zero. The Groundfish Plan Teams (GPTs) and groundfish Tier 5 assessment authors have explored several alternative approaches to dealing with zeros in the data, including: 1) excluding them from the model fit (i.e., treating the associated surveys as "missing"), 2) replacing the zeros with small values for the estimates and large values for the associated cv's, and 3) fitting the data using a Tweedie, rather than lognormal, distribution to characterize the observation error (Monnahan et al. 2021). The GPTs' currently accepted method for dealing with zeros in a time series is alternative 1 (Jane Sullivan, AFSC, pers. comm.).

This 2023 assessment fits the SS/RE RW model to the survey data using the rema R package (version 0.1.0; Sullivan (2022)). Model runs were completed for each of the three approaches noted above to dealing with zeroes in the data ("0s as NAs","small values", and "Tweedie") using the default settings for each approach. The author recommends adopting the GPTs' accepted method for this assessment: alternative 1, 0's as NAs. This is an area for coordinating future research with assessment authors and the CPT and GPTs.

### 6.2.2 MMB-at-mating

Annual estimates of MMB-at-mating $\left(M M B_{y}^{a m}\right)$ are calculated from the SS/RE RW estimates of MMB at the time of the annual NMFS EBS bottom trawl survey by accounting for natural and fishing mortality from the time of the survey to mating (nominally February 15 of the following
year). Given the SS/RE RW estimates $<M M B_{y}^{s}>$ of MMB at the time of the survey in year $y, M M B_{y}^{a m}$ was calculated from $M M B_{y}^{s}, M M B_{y}^{b f}$ (MMB just before the fisheries), and $M M B_{y}^{a f}$ (MMB just after the fisheries, which are assumed to occur instantaneously as a simplification), using:

$$
\begin{gather*}
M M B_{y}^{b f}=<M M B_{y}^{s}>\cdot e^{-M \cdot t_{s f}}  \tag{7}\\
M M B_{y}^{a f}=M M B_{y}^{b f}-R M_{y}-D M_{y}^{M M}  \tag{8}\\
M M B_{y}^{a m}=M M B_{y}^{a f} \cdot e^{-M \cdot t_{f m}} \tag{9}
\end{gather*}
$$

where $M$ is natural mortality, $R M_{y}$ is retained catch mortality on MMB in the directed fishery in year $y, D M_{y}^{M M}$ is discard mortality on mature males (not on all crab) in all fisheries in year $y, t_{s f}$ is the time between the survey and the fishery, $t_{f m}$ is the time between the fishery and mating.

### 6.3 Model Selection and Evaluation

### 6.3.1 MMB at the time of the survey

All three $\mathrm{SS} /$ RE RW models for survey MMB achieved acceptable maximum gradients and are considered to have converged (Table 16). Estimated process errors, $\phi$, are similar between the three SS/RE RW models and appear reasonable (Table 17). Given that the Tweedie parameter is limited to the range $[1,2]$, the confidence interval associated with its estimate indicates the parameter may not be well-estimated (Table 17). The MCMC results for the ln-scale process error (i.e., $\lambda$ ), the ln-scale terminal year survey year, and the arithmetic-scale terminal year survey biomass (Figures $30-35)$ do not indicate any issues with the non-Tweedie models. MCMC results were not produced for the model using the Tweedie option; the MCMC process was terminated after running for 24 hours without completion (MCMC for the Tweedie option is known to take a long time for some models; Jane Sullivan, AFSC, pers. comm.).

The SS/RE RW models appear to fit the survey MMB data well through most of the time series, but the "zeros as NAs" and "Tweedie" models do not fit the declining trend in the data during the final two years (Tables 18-21; Figures 36-37). One-step-ahead (OSA) residuals are shown in Figures 38 and 39 for the non-"Tweedie" models; OSAs for the rema model are considered an improved method over Pearson's residuals for assessing model fit. The OSA residuals are slightly negative.

### 6.3.2 MMB-at-mating

MMB-at-mating was estimated using results from the "zeros as NAs" SS/RE RW model for MMB at the time of the survey (as per GPT-approved practice when dealing with zeros in the data being fit). Estimated MMB-at-mating was highest at the start of the time series (1975/76; 23,282 t) and declined rapidly until 1985/86 (1,003 t), after which it increased slowly, reaching a lower peak in 1993/94 (3,876 t) (Table 22, Figure 40). A subsequent decline started in 1995/1996. Since 2004/05,

MMB-at-mating has fluctuated at a very low level (250 t). Following the initial period of large catches and concurrent high survey biomass in 1975/76-1984/85, fishing mortality has had little effect on the estimated MMB-at-mating since 1985/86. Estimated MMB-at-mating for 2022/23 is 180 t.

## 7 Calculation of the OFL

### 7.1 Tier Level:

In 2013 the CPT and SSC designated PIBKC as a Tier 4 for status determination, defined by Amendment 24 to the Fishery Management Plan for the Bering Sea/Aleutian Islands King and Tanner Crabs (NPFMC 2008a), based on data availability.

### 7.2 Parameters and stock sizes

### 7.3 OFL specification

### 7.3.1 Stock status level

The minimum stock size threshold (MSST) for Tier 4 stocks is specified as $\frac{1}{2} B_{M S Y}$ (or a proxy thereof, $B_{M S Y_{\text {proxy }}}$ ). If $B$ drops below the MSST, the stock is considered to be overfished. The stock status level is based on the ratio of "current" spawning stock biomass ( $B$ ) to $B_{M S Y}$. Maximum Sustainable Yield (MSY) is the largest long-term average catch or yield that can be taken from a stock or stock complex under prevailing ecological and environmental conditions. The fishing mortality that, if applied over the long-term, would result in MSY is $F_{M S Y} . B_{M S Y}$ is the longterm average stock size when fished at $F_{M S Y}$, and is based on mature male biomass at the time of mating ( $M M B_{\text {mating }}$ ), which serves as a proxy for egg production. $M M B_{\text {mating }}$ is used as a basis for $B_{M S Y}$ because of the complicated female crab life history, unknown sex ratios, and male-only fishery.

Although $B_{M S Y}$ cannot be calculated for a Tier 4 stock, a proxy value ( $B_{M S Y_{\text {proxy }}}$ ) is defined as the average biomass over a specified time period that satisfies the conditions under which $B_{M S Y}$ would occur (i.e., equilibrium biomass yielding MSY under an applied $F_{M S Y}$ ). The time period for establishing $B_{M S Y_{p r o x y}}$ is assumed to be representative of the stock being fished at an average rate near $F_{M S Y}$ and fluctuating around $B_{M S Y}$. The SSC has previously endorsed using the time periods 1980-84 and 1990-97 to calculate $B_{M S Y_{p r o x y}}$ for PIBKC to avoid time periods of low abundance possibly caused by high fishing pressure (Figure 41). Alternative time periods (e.g., 1975 to 1979) have also been considered, but these were rejected (Foy 2013). Considerations for choosing the averaging time period include the following:

## Production potential

1) Between 2006 and 2013 the stock appeared to be below a threshold for responding to increased production based on the lack of response of the adult stock biomass to slight fluctuations in recruitment (male crab 120-134 mm; Figure 20 in Foy (2013)). The stock appears to have remained below this (unknown) threshold to the present.
2) An estimate of surplus production using the equation

$$
A S P_{t}=M M B_{t+1}-M M B_{t}+C_{t}
$$

where $C_{t}$ denotes total catch mortality in year $t$ suggested that meaningful surplus production existed only in the late 1970s and early 1980s, while minor surplus production in the early 1990s may have led to the increases in biomass observed in the late 1990s.
3) Although climate regime shifts where temperature and current patterns change are likely to impact blue king crab larval dispersal and subsequent juvenile crab distribution, no apparent trends in production before or after 1978 were observed (Foy 2013). There are few empirical data to identify trends that may indicate a production shift.

## Exploitation rates

Exploitation rates fluctuated during the open fishery periods from 1975 to 1987 and 1995 to 1998 (Figure 20 in Foy (2013)) while total catch increased until 1980, then decreased until the fishery was closed in 1987 (Figure 4). Following the re-opening of the fishery in 1995, total catch declined annually until the fishery was closed again in 1999. The current $F_{M S Y_{\text {proxy }}}=M$ is $0.18 \mathrm{yr}^{-1}$, so time periods with greater exploitation rates should not be considered to represent periods with average rates of fishery removals.

## Recruitment

After increases in exploitation rates in the late 1980s and 1990s, estimates of $\ln$ (recruits/MMB) dropped, suggesting that exploitation rates at the levels of $F_{M S Y_{\text {proxy }}}=M$ were not sustainable (Foy 2013).

In Tier 4, the "total catch OFL" and the "retained catch OFL" are calculated by applying the $F_{\text {OFL }}$ to all crab at the time of the fishery (total catch OFL) or to the legal portion of the stock (retained catch OFL). The stock status level ( $\mathrm{a}, \mathrm{b}$ or c ) is based on the ratio of $B$ to $B_{M S Y_{\text {proxy }}}$, and determines the $F_{\text {OFL }}$ based on the Tier $4 F_{\text {OFL }}$ Control Rule (Figure 42) as described in the following table:

The Tier $4 F_{O F L}$ Control Rule (see also Figure 42).

| Level | $B / B_{M S Y_{\text {proxy }}}$ | $F_{O F L}$ |
| :--- | :--- | :--- |
| a. | $B / B_{M S Y_{\text {proxy }}}>1.0$ | $F_{O F L}=\gamma \cdot M$ |
| b. | $\beta<B / B_{M S Y_{\text {proxy }}} \leq 1.0$ | $F_{O F L}=\gamma \cdot M\left[\left(B / B_{M S Y_{\text {proxy }}}-\alpha\right) /(1-\alpha)\right]$ |
| c. | $B / B_{M S Y_{\text {proxy }} \leq \beta} \leq \beta$ | $F_{\text {directed }}=0, F_{\text {OFL }} \leq F_{M S Y}$ |

When $B / B_{M S Y_{\text {proxy }}}$ is greater than 1 (Stock Status Level a), $F_{O F L_{\text {proxy }}}$ is given by the product of a scalar ( $\gamma$, nominally equal to 1.0 ) and $M$. When $B / B_{M S Y_{p r o x y}}$ is less than 1 and greater than the critical threshold $\beta(=0.25)$ (Stock Status Level b), the scalar $\alpha(=0.1)$ determines the slope of the non-constant portion of the control rule for $F_{O F L_{\text {proxy }}}$. When the ratio $B / B_{M S Y_{\text {proxy }}}$ drops below $\beta$ (Stock Status Level c), directed fishing mortality is set to zero. Values for $\alpha$ and $\beta$ (0.1 and 0.25 , respectively) are based on a sensitivity analysis of the effects on $B / B_{M S Y_{p r o x y}}$ (NMFS 2008). Because the stock is overfished when $B<\operatorname{MSST}$, the stock may be overfished when the stock is level "b" but it is certainly overfished when the level is "c".

In this assessment, $B_{M S Y_{\text {proxy }}}$ is the average of $M M B_{\text {mating }}$ over the years $\{1980: 1984,1990: 1997\}$ (see Figure 41), i.e., $4,196 \mathrm{t}$. Because MMB-at-mating for $2022 / 23$ is 180.4 t , the current stock status ratio is 0.0430078 and the stock is "overfished". The Tier level is Tier 4c.

### 7.3.2 Basis for MMB-at-mating

The basis for projecting MMB from the survey to the time of mating for years prior to the assessment year is discussed in detail the Model Description section above (Section 6.2.2). For the assessment year, $2023 / 24$, the fishery has not yet occurred so $R M$ and $D M$ are unknown. The amount of fishing mortality depends on the (as yet-to-be-determined) overfishing limit, so an iterative procedure is used to estimate MMB-at-mating. This procedure involves:

1. "guess" a value for $F_{O F L}$, the directed fishing mortality rate that yields OFL $\left(F_{O F L_{\max }}=\gamma \cdot M\right.$ is used)
2. determine the OFL corresponding to fishing at $F_{O F L}$ using the following equations:

- $M M B_{f}=M M B_{s} \cdot e^{-M \cdot t_{s f}}$
- $R M_{O F L}=\left(1-e^{-F_{O F L}}\right) \cdot M M B_{s} \cdot e^{-M \cdot t_{s f}}$
- $D M_{O F L}=\theta \cdot \frac{M M B_{f}}{p_{\text {male }}}$
- $O F L=R M_{O F L}+D M_{O F L}$

3. project MMB-at-mating from the "current" survey MMB and the OFL:

- $M M B_{m}=\left[M M B_{f_{y}}-\left(R M_{O F L}+p_{\text {male }} \cdot D M_{O F L}\right)\right] \cdot e^{-M \cdot t_{f m}}$

4. use the harvest control rule to determine the $F_{O F L}$ corresponding to the projected MMB-atmating.
5. update the "guess" in 1. for the result in 4.
6. repeat steps 2-5 until the process has converged, yielding self-consistent values for $F_{O F L}$ and $B$.

In this procedure, $p_{\text {male }}$ is the fraction of discard mortality on males (taken to be 0.5). Note that this procedure determines the OFL for the assessment year as well as the (projected) MMB-atmating. Also note that, while the retained mortality $R M_{O F L}$ is based on the $F_{O F L}$, the discard mortality $D M_{O F L}$ is assumed to be proportional to the MMB at the time of the fishery, with proportionality constant $\frac{\theta}{p_{\text {male }}}$.
The value of MMB at the time of the survey for the / fishing year is 201 t , Table 23). The constant $\theta$ was determined by the average ratio of discard mortality on MMB ( $D M_{M M B}$ ) to MMB at the time of the fishery $\left(M M B_{f}\right)$ over a recent time interval:

$$
\theta=\frac{1}{N} \sum_{y} \frac{D M_{M M B_{y}}}{M M B_{f_{y}}}
$$

where the sum is over the last N years. The value for $\theta$ used for this assessment is $3.0233236 \times 10^{-4}$, based on averaging over the last 3 years (Table 23).

### 7.3.3 Specification of $F_{O F L}$, OFL and other applicable measures

The iterative calculations to determine the Tier $4 F_{O F L}$, OFL, and related measures are described in the previous section. Parameters for the calculations are listed in Table 23. The results are given in Table 24. Projected MMB-at-mating for crab fishery year / is 180.5 t and the associated status ratio is 0.043. Consequently, the stock is projected to be in Tier 4c, with $F_{O F L}=0$ (directed fishing is prohibited). The resulting Tier 4 OFL would be 0.116 t .

The following tables summarize the basis for the OFL (repeating Tables C and D).
Basis for the OFL (biomass units in metric tons).

| Year | Tier | $B_{M S Y}$ | $B$ | $B / B_{M S Y}$ | $\gamma$ | Years to define $B_{M S Y}$ | M | $\mathrm{P}^{*}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $2019 / 20$ | 4 c | 4,099 | 180 | 0.044 | 1 | $1980 / 81-1984 / 85 ; 1990 / 91-1997 / 98$ | 0.18 | $25 \%$ buffer |
| $2020 / 21$ | 4 c | 4,099 | 181 | 0.044 | 1 | $1980 / 81-1984 / 85 ; 1990 / 91-1997 / 98$ | 0.18 | $25 \%$ buffer |
| $2021 / 22$ | 4 c | 4,099 | 180 | 0.044 | 1 | $1980 / 81-1984 / 85 ; 1990 / 91-1997 / 98$ | 0.18 | $25 \%$ buffer |
| $2022 / 23$ | 4 c | 4,099 | 180 | 0.044 | 1 | $1980 / 81-1984 / 85 ; 1990 / 91-1997 / 98$ | 0.18 | $25 \%$ buffer |
| $2023 / 24$ | 4 c | 4,196 | 181 | 0.043 | 1 | $1980 / 81-1984 / 85 ; 1990 / 91-1997 / 98$ | 0.18 | $25 \%$ buffer |

Basis for the OFL (biomass units in millions of lbs).

| Year | Tier | $B_{M S Y}$ | $B$ | $B / B_{M S Y}$ | $\gamma$ | Years to define $B_{M S Y}$ | M | $\mathrm{P}^{*}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $2019 / 20$ | 4 c | 9.052 | 0.3976 | 0.044 | 1 | $1980 / 81-1984 / 85 ; 1990 / 91-1997 / 98$ | 0.18 | $25 \%$ buffer |
| $2020 / 21$ | 4 c | 9.052 | 0.3981 | 0.044 | 1 | $1980 / 81-1984 / 85 ; 1990 / 91-1997 / 98$ | 0.18 | $25 \%$ buffer |
| $2021 / 22$ | 4 c | 9.037 | 0.3976 | 0.044 | 1 | $1980 / 81-1984 / 85 ; 1990 / 91-1997 / 98$ | 0.18 | $25 \%$ buffer |
| $2022 / 23$ | 4 c | 9.037 | 0.3976 | 0.044 | 1 | $1980 / 81-1984 / 85 ; 1990 / 91-1997 / 98$ | 0.18 | $25 \%$ buffer |
| $2023 / 24$ | 4 c | 9.2500 | 0.3980 | 0.043 | 1 | $1980 / 81-1984 / 85 ; 1990 / 91-1997 / 98$ | 0.18 | $25 \%$ buffer |

### 7.3.4 Specification of the retained catch portion of the total catch OFL

The retained portion of the total catch OFL for this stock is 0 t .

### 7.3.5 Recommendations

No alternative models were considered for this assessment: the methods used to determine stock status are the same as those used in the previous assessment. Based on this Tier 4 approach, and similar to conclusions reached in recent assessments, MMB-at-mating remains at historically low levels such that the stock is in Tier 4 c , requiring that the directed fishery be closed and that $F_{O F L}$ be set such that it is less than $F_{M S Y}$. The rebuilding analysis (NMFS 2008) concluded that an OFL of 1.16 t ( 0.0026 million lbs), corresponding to a current fishing mortality rate of roughly 0.006 $\mathrm{yr}^{-1}$, would be consistent with this requirement on $F_{O F L}$ while allowing for a minimal amount of bycatch such that fisheries for other crab or groundfish targets could be be prosecuted. The author recommends continuing to use this approach.

## 8 Calculation of the $A B C$

To calculate an Annual Catch Limit (ACL) to account for scientific uncertainty in the OFL, an acceptable biological catch (ABC) control rule was developed such that ACL=ABC. For Tier 3 and 4 stocks, the ABC is set below the OFL by a proportion based on a predetermined probability that the ABC would exceed the OFL $\left(\mathrm{P}^{*}\right)$. Currently, $\mathrm{P}^{*}$ is set at 0.49 and represents a proportion of the OFL distribution that accounts for within-assessment uncertainty ( $\sigma_{w}$ ) in the OFL to establish the maximum permissible $\mathrm{ABC}\left(\mathrm{ABC}_{\text {max }}\right)$. Any additional uncertainty to account for uncertainty outside of the assessment methods is considered as a recommended ABC below $\mathrm{ABC}_{\text {max }}$. For the PIBKC stock, the SSC has approved a constant buffer of $25 \%$ to the OFL (NPFMC 2014b).

### 8.1 Specification of the probability distribution of the OFL used in the ABC

The OFL was set based on a Tier 5 calculation of average catch mortalities between 1999/2000 and 2005/06 to adequately reflect the conservation needs with this stock and to acknowledge the existing non-directed catch mortality. As such, the OFL does not have an associated probability distribution.

### 8.2 List of variables related to scientific uncertainty considered in the OFL probability distribution

None. The OFL is based on a Tier 5 calculation and does not have an associated probability distribution. However, compared to other BSAI crab stocks, the uncertainty associated with the estimates of stock size and OFL for Pribilof Islands blue king crab is very high due to insufficient data and the small spatial extent of the stock relative to the survey sampling density. The coefficient of variation (cv) for the design-based estimate of survey MMB for the most recent survey (2022) is 0.7022 , and has ranged between 0.17 and 1.00 . The corresponding cv for the RW model-estimated MMB is 0.4512 .

### 8.3 List of additional uncertainties considered for alternative $\sigma_{b}$ applications to the ABC

No alternative $\sigma_{b}$ applications were considered, but several sources of uncertainty are not included in the measures of uncertainty reported as part of the stock assessment:

- Natural mortality is pre-specified, not estimated. Survey catchability is essentially treated as 1 , and not estimated.
- $F_{M S Y}$ is assumed to be equal to $\gamma \cdot M$ when applying the OFL control rule, where the proportionality constant $\gamma$ is assumed to be equal to 1.0 and $M$ is assumed to be known.
- $B_{M S Y}$ is assumed to be equivalent to average mature male biomass. However, stock biomass has fluctuated greatly and targeted fisheries only occurred from 1973-1987 and 1995-1998, so considerable uncertainty exists with this estimate of $B_{M S Y}$.

### 8.4 Recommendations

For $2023 / 24 F_{\text {directed }}=0$ and the total catch OFL is based on the catch biomass that would address the conservation needs for this stock while acknowledging the existing non-directed catch mortality. In this case, the $A B C$ based on a $25 \%$ buffer of the average catch between 1999/2000 and $2005 / 2006$ would be 0.870 t . The following tables repeat the information in Tables A and B.

Management performance (in metric tons).

| Year | MSST | Biomass | TAC | Retained Catch | Total Catch Mortality | OFL | ABC | yr |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | ---: |
| $2020 / 21$ | 2,049 | 181 | closed | 0 | 0 | 1.16 | 0.87 | 2020 |
| $2021 / 22$ | 2,098 | 235 | closed | 0 | 0.102 | 1.16 | 0.87 | 2021 |
| $2022 / 23$ | 2,098 | 180 | closed | 0 | 0.25 | 1.16 | 0.87 | 2022 |
| $2023 / 24$ | - | 181 | closed | - | - | 1.16 | 0.87 | 2023 |
| $2024 / 25$ | - | 181 | closed | - | - | 1.16 | 0.87 | 2024 |

Management performance (in millions of lbs).

| $2023 / 24$ | - | 0.3980 | closed | - | - | 0.0026 | 0.0019 | 2023 |
| $2024 / 25$ | - | 0.3980 | closed | - | - | 0.0026 | 0.0019 | 2024 |

## 9 Rebuilding Analyses

A revised rebuilding analysis was submitted to the U.S. Secretary of Commerce in 2014 because NMFS determined that the stock was not rebuilding in a timely manner and would not meet the rebuilding horizon of 2014. The Secretary approved the plan in 2015, as well as the two
amendments that implement the revised plan (Amendment 43 to the King and Tanner Crab Fishery Management Plan and Amendment 103 to the BSAI Groundfish Fishery Management Plan). These amendments impose a closure to all fishing for Pacific cod with pot gear in the Pribilof Islands Habitat Conservation Zone. This measure was designed to protect the main concentration of the stock from the fishery with the highest observed rates of bycatch (NPFMC 2014a). The area has been closed to trawling since 1995.

A recently-developed qualitative network model that describes important biological interactions that may influence the productivity of PIBKC (Reum et al. 2020) found that, under a scenario of no projected climate change, predicted increases in PIBKC were reliable only when stock enhancement was implemented in a PIBKC hatchery-program scenario. However, when climate change was accounted for, stock enhancement could not counteract the adverse impacts of climate, which had an overall negative effect on BKC. Thus, a stock enhancement program for PIBKC may be a necessary, but not sufficient, requirement for rebuilding to occur.

The revised (2014) rebuilding plan does not have a target rebuild date and NMFS cannot predict when or if rebuilding will occur (NMFS 2022). There is no new and unexpected information that would significantly alter the rebuilding expectations. The recent trajectory of the time series of MMB-at-survey time provides no evidence of an increasing trend. Further, survey size compositions provide no evidence for recent recruitment to the stock. The failure of the EBS shelf survey to catch any mature males this year does not raise the level of concern for this stock above what it has been in the recent past; the survey does not target blue king crab and the result is consistent with sampling a population at low (but non-zero) abundance. The causes of the continued low abundance and failure to recover are not well understood, but are thought to be predominantly due to environmental changes that inhibit recruitment. In April 2022, the Regional Administrator made the determination that PIBKC was "not making inadequate progress" towards rebuilding (NMFS 2022).

## 10 Data Gaps and Research Priorities

The best way to handle the MMB time series when the NMFS EBS shelf survey fails to capture any mature male crab needs to be explored in coordination with the CPT, the GPTs, and other assessment authors because this issue occurs with other stocks.

Given the large CVs associated with the survey abundance and biomass estimates for PIBKC, assessment of this species might benefit from additional surveys using alternative gear at finer spatial resolution. Other data gaps include stock-specific natural mortality rates and a lack of understanding regarding processes apparently preventing successful recruitment to the Pribilof District.

Jared Weems, as a PhD student at University of Alaska Fairbanks, conducted research on alternative survey designs, including visual censuses, drop camera, and collector traps to better quantify PIBKC in a study funded by NPRB. Study results were presented to the CPT in September 2020. The objectives of the project were to 1) quantify supply and abundance of early juvenile stages of blue king crab and red king crab, 2) assess habitat availability in nearshore St. Paul Island areas relative to historical survey sites, and 3) identify juvenile king crab predators and predation potential. To assess abundance, Weems compared historical (a 1980s habitat study) bottom
trawl and rock dredge young-of-the-year (YOY) crab abundance data to current abundance levels via settlement collector bags and scuba diver visual surveys. Historical results showed YOY BKC occurred at relatively high abundance levels in St Paul Island nearshore areas ( $\mathrm{N}=514$ YOY), whereas current abundance levels were low ( $\mathrm{N}=8$ YOY). Historical bottom trawl and rock dredge benthic habitat data were compared to current habitat assessed via scuba diver and drop camera surveys. Benthic habitat complexity matched in $87 \%$ of the locations that were sampled in both time periods, so there was little suggestion of habitat degradation with time. In the current study, though, no PIBKC were found in shellhash substrate, an important settlement and nursery habitat for juvenile PIBKC, which occurred in relatively high density on the east and southern sides of St. Paul Island. Overall, with respect to PIBKC recruitment limitation in the Pribilof Islands, this study suggested that 1) BKC abundance is limiting, but that 2) benthic habitat is non-limiting and relatively unchanged over time.

Jonathan Reum (AFSC) and colleagues have developed a qualitative network model that describes important biological interactions that may influence the productivity of PIBKC (Reum et al. 2020). The purpose was to explore the potential efficacy of different management interventions that include new policies on fisheries that target the predators/competitors of PIBKC, as well as out-stocking of benthic PIBKC juveniles assuming implementation of a hatchery program, in the context of predicted future climate change. As noted in Section H, (Reum et al. 2020) found that predicted increases in BKC under a scenario of no future climate change were reliable only when stock enhancement was implemented in a BKC hatchery-program. However, when climate change was accounted for, stock enhancement could not counteract the adverse impacts of climate, which had an overall negative effect on BKC. Other management scenarios considered related to changes in fishing effort on BKC predators. For those scenarios, BKC outcomes were unreliable, but climate change further decreased the probability of observing recovery. The study concluded that the largest gains in prediction precision would be made by reducing uncertainty associated with ecological interactions between adult blue and red king crab.

Given these studies, it may be worthwhile to: 1) develop a program to better identify critical nursery habitat within the Pribilof Islands and to characterize postlarval supply to, and settlement abundance in, these areas for both blue and red king crab, and 2) better characterize ecological interactions between adult blue and red king crab.

## 11 Acknowledgments

I would like to acknowledge the particular contributions to this assessment made by Jon Richar (AFSC Kodiak) and all personnel contributing to the planning and execution of the (and previous) NMFS EBS shelf bottom trawl survey(s), as well as Ben Daly (ADF\&G) for providing crab fishery catch information. Jane Sullivan (AFSC Juneau) provided help with the rema package and explained the Groundfish Plan Teams current approach to dealing with zeros when fitting time series data with the package. Melissa Haltuch (AFSC Seattle) and Bill Bechtol (UAF Homer) provided helpful reviews of the document.

## Tables

## List of Tables

$$
1 \quad \begin{aligned}
& \text { Retained catch and average CPUE (number of legal males/pot lift) of PIBKC in the } \\
& \text { directed pot fishery, 1973-1998/99. The directed fishery has been closed since the } \\
& \text { 1999/2000 fishing season. NA: not applicable (no directed fishery) . . . . . . . . . } 35
\end{aligned}
$$

2 Bycatch catch of PIBKC in the directed and other crab fisheries, as estimated from
crab observer data. A discard mortality rate of 0.2 was applied to obtain discard
mortalities. Units are $t$. ..... 37
3 Bycatch of PIBKC in the groundfish fisheries, by gear type. Biomass and (discard) mortality are in kilograms. Number of vessels and bycatch in numbers are only available after 2008/09. Discard mortality rates of 0.2 and 0.8 for fixed and trawl gear, respectively, were applied to obtain discard mortalities. ..... 38
4 Bycatch (numbers of crab) of PIBKC in the groundfish fisheries, by target type (avalable only after 2008/09). Discard mortality rates were not applied. ..... 39
5 Bycatch (biomass, in kg ) of PIBKC in the groundfish fisheries, by target type (aval- able only after 2008/09). Discard mortality rates were not applied. ..... 40
$6 \quad$ Discard mortality (in kg ) of PIBKC in the groundfish fisheries, by target type.Discard mortality rates of 0.2 and 0.8 for fixed and trawl gear, respectively, were applied to obtain discard mortalities. ..... 41
$7 \quad$ Size groups for various male components of the PIBKC stock used here. Female maturity is based on abdominal flap morphology and egg presence. ..... 42
8 Sample sizes (number of survey hauls, number hauls where crab were caught, number of crab caught) for male population components in the NMFS EBS trawl survey in the Pribilof District. ..... 43
9 Sample sizes (number of survey hauls, number hauls where crab were caught, number of crab caught) for female population components in the NMFS EBS trawl survey in the Pribilof District. ..... 45
10 Summary statistics for trawl survey abundance by decade, in millions. ..... 47
11 Summary statistics for trawl survey biomass by decade, in $1,000 \mathrm{st}$. ..... 48
12 Estimated annual abundance (millions of crab) of male PIBKC population compo- nents from the NMFS EBS trawl survey. ..... 49
13 Estimated annual abundance (millions of crab) of female PIBKC population compo- nents from the NMFS EBS trawl survey ..... 51
14 Estimated annual biomass (1,000s t) of male PIBKC population components from the NMFS EBS trawl survey. ..... 53
15 Estimated annual biomass ( $1,000 \mathrm{st}$ ) of female PIBKC population components from the NMFS EBS trawl survey. ..... 55
16 Maximum objective function gradient after SS/RE RW model optimization, by "ze- ros option". ..... 57
17 Maximum objective function gradient after SS/RE RW model optimization, by "ze- ros option". ..... 58
18 "Zeros as NAs" model fits to mature male survey biomass (in t). lci: lower confidence bound; uci: upper confidence bound; observed: design-based survey estimates; base: model results from last assessment; model: "Zeros as NAs" model results. Confidence intervals are $80 \%$. ..... 59

19 "Small constant" model fits to mature male survey biomass (in t; 1975-2019). lci: lower confidence bound; uci: upper confidence bound; observed: design-based survey estimates; base: model results from last assessment; model: "small constant" model results. Confidence intervals are $80 \%$.
20 "Small constant" model fits to mature male survey biomass (in t; 2020-2023). lci: lower confidence bound; uci: upper confidence bound; observed: design-based survey estimates; base: model results from last assessment; model: "small constant" model results. Confidence intervals are $80 \%$.62

21 "Tweedie" model fits to mature male survey biomass (in t). lci: lower confidence bound; uci: upper confidence bound; observed: design-based survey estimates; base: model results from last assessment; model: "Tweedie" model results. Confidence intervals are $80 \%$.
22 Components in calculation of MMB-at-mating time series, as well as MMB-at-mating calculated for the last assessment. Fishing mortality is only on mature males. All values are in $t$.65
23 Values required to determine the Tier 4 OFL. ..... 66

24 Results from the Tier 4 OFL determination. $R M_{O F L}=$ retained catch portion of the OFL, $D M_{\text {OFL }}=$ discard mortality portion of the OFL used to determine $B$ ("current") MMB-at-mating for 2023/24.

Table 1. Retained catch and average CPUE (number of legal males/pot lift) of PIBKC in the directed pot fishery, 1973-1998/99. The directed fishery has been closed since the 1999/2000 fishing season. NA: not applicable (no directed fishery)

Table 23. Values required to determine the Tier 4 OFL.

|  | quantity | value | units | description |
| ---: | ---: | ---: | ---: | ---: |
| 1 | $M M B_{s}$ | 201 | t | current survey MMB |
| 2 | $B_{M S Y}$ | 4,196 | t | Tier 4 $B_{M S Y}$ proxy |
| 3 | $\theta$ | 0.000302 | - | mean MMB exploitaion ratio |
| 4 | M | 0.18 | year $^{-1}$ | assumed natural mortality |
| 5 | $\gamma$ | 1 | - | control rule parameter |
| 6 | $\alpha$ | 0.1 | - | control rule parameter |
| 7 | $\beta$ | 0.25 | - | control rule parameter |
| 8 | $t_{s f}$ | 0.25 | years | time from survey to fishery |
| 9 | $t_{f m}$ | 0.333 | years | time from survey to fishery |

Table 24. Results from the Tier 4 OFL determination. $R M_{O F L}=$ retained catch portion of the OFL, $D M_{O F L}=$ discard mortality portion of the OFL used to determine $B$ ("current") MMB-at-mating for 2023/24.

|  | quantity | units | value |
| :--- | ---: | ---: | ---: |
| 1 | $B$ | t | 181 |
| 2 | $B_{M S Y}$ | t | 4,196 |
| 3 | stock status | - | overfished |
| 4 | $F_{\text {OFL }}$ | year $^{-1}$ | 0 |
| 5 | $R M_{\text {OFL }}$ | t | 0 |
| 6 | $D M_{\text {OFL }}$ | t | 0.116 |
| 7 | OFL | t | 0.116 |

## Figures

## List of Figures

1 Distribution of blue king crab, Paralithodesplatypus, in Alaskan waters. ..... 71
2 Map of the ADF\&G King Crab Registration Area Q (Bering Sea), showing (amongothers) the Pribilof District, which constitutes the stock boundary for PIBKC. Thefigure also indicates NMFS EBS Shelf survey grid (squares and circles), the originalarea used to calculate survey biomass and fishery catch data (shded in grey) in thePribilof District, and the additional 20 nm strip (red dotted line) added in 2013. . .72
3 The shaded area shows the Pribilof Islands Habitat Conservation Zone (PIHCZ). Trawl fishing is prohibited year-round in this zone (as of 1995), as is pot fishing for Pacific cod (as of 2015). Also shown is a portion of the NMFS annual EBS bottom trawl survey grid (squares and circles). ..... 73
4 Retained catch and discard mortality, in t , for PIBKC in the crab fisheries. A discard mortality rate of 0.2 was used to convert bycatch biomass to mortality. The lower plot shows discard mortality in the crab fisheries on an expanded $y$-axis scale to show annual details. ..... 74
5 Upper plot: Bycatch of PIBKC in the groundfish fisheries since 1991/92 by gear type (no mortality applied). Lower plot: Discard mortality of PIBKC in the groundfish fisheries since 1991/92 by gear type. Gear-specific discard mortality rates of 0.2 and 0.8 were applied to bycatch from fixed and trawl gear, respectively ..... 75
6 Upper plot: Bycatch of PIBKC in the groundfish fisheries since 2009/10 by gear type (no mortality applied). Lower plot: Discard mortality of PIBKC in the groundfish fisheries since 2009/10 by gear type. Gear-specific discard mortality rates of 0.2 and 0.8 were applied to bycatch from fixed and trawl gear, respectively ..... 76
7 Upper plot: Bycatch of PIBKC in the groundfish fisheries since 2009/10 by target type (no mortality applied). Lower plot: Discard mortality of PIBKC in the ground- fish fisheries since 2009/10 by target type. Gear-specific discard mortality rates of 0.2 and 0.8 were applied to bycatch from fixed and trawl gear, respectively ..... 77
8 Estimated bycatch of PIBKC in the groundfish trawl gear fisheries by ADF\&G stat area, expanded from groundfish observer reports. Red line: boundary of the PIHCZ. ..... 78
9 Estimated bycatch of PIBKC in the groundfish fixed gear fisheries by ADF\&G stat area, expanded from groundfish observer reports. Red line: boundary of the PIHCZ. ..... 79
10 NMFS EBS Shelf Survey stations in the Pribilof District (large dots), the survey station grid (thin black lines), and the Pribilof Islands Habitat Conservation Zone (orange outline). ..... 80
11 NMFS survey abundance time series for male PIBKC, by maturity category. ..... 81
12 NMFS survey abundance time series for male PIBKC, by fishery category. ..... 82
13 NMFS survey abundance time series for male PIBKC, by population category, from 2010 ..... 83
14 NMFS survey abundance time series for male PIBKC, by fishery category, from 2010. ..... 84
15 NMFS survey abundance time series for female PIBKC, by population category. The values for mature and all females for 1980 are off-scale to better show details of remaining values. ..... 85
16 NMFS survey abundance time series for female PIBKC, by population category, from 2010. ..... 86
17 NMFS survey biomass time series for male PIBKC, by maturity category. ..... 87
18 NMFS survey biomass time series for male PIBKC, by fishery category. ..... 88
19 NMFS survey biomass time series for male PIBKC, by maturity category, from 2010. ..... 89
20 NMFS survey biomass time series for male PIBKC, by fishery category, from 2010. ..... 90
21 NMFS survey biomass time series for female PIBKC, by population category. The values for mature and all females for 1980 are off-scale to better show details of remaining values. ..... 91
22 NMFS survey biomass time series for female PIBKC, by population category, from 2010. ..... 92
23 Annual size compositions for PIBKC in the NMFS EBS trawl survey, by sex, over the entire survey period. The survey was not conducted in 2020. ..... 93
24 Annual size compositions for PIBKC in the NMFS EBS trawl survey, by sex, over the entire survey period, except that females in 1980 have been removed to show detail. The survey was not conducted in 2020. ..... 94
25 Annual size compositions for PIBKC in the NMFS EBS trawl survey, by sex, since 2006. The survey was not conducted in 2020. ..... 95
26 Decadal-average abundance CPUE (number/sq-nmi) by for male PIBKC in the NMFS EBS trawl survey. ..... 96
27 Decadal-average abundance CPUE (number/sq-nmi) by for female PIBKC in the NMFS EBS trawl survey. ..... 97
28 Decadal-average biomass CPUE ( $\mathrm{t} / \mathrm{sq}-\mathrm{nmi}$ ) by for male PIBKC in the NMFS EBS trawl survey ..... 98
29 Decadal-average biomass CPUE ( $\mathrm{t} / \mathrm{sq}-\mathrm{nmi}$ ) by for female PIBKC in the NMFS EBS trawl survey ..... 9930 MCMC diagnostics for the ln-scale process error parameter from the "zeros as NAs"model. Top row: trace plot; center row: autocorrelation plot; bottom row: histogram(left) and estimated posterior density with median (vertical line) and $80 \%$ confidenceinterval (shading). rHat ( $<1.05$ ) and ESS ( $>100$ ) are measures of acceptable MCMCmixing.100
31 MCMC diagnostics for the ln-scale process error parameter from the "small constant"model. Top row: trace plot; center row: autocorrelation plot; bottom row: histogram(left) and estimated posterior density with median (vertical line) and $80 \%$ confidenceinterval (shading). rHat ( $<1.05$ ) and ESS ( $>100$ ) are measures of acceptable MCMCmixing.101
32 MCMC diagnostics for the ln-scale terminal year survey MMB from the "zeros asNAs" model. Top row: trace plot; center row: autocorrelation plot; bottom row:histogram (left) and estimated posterior density with median (vertical line) and$80 \%$ confidence interval (shading). rHat ( $<1.05$ ) and ESS $(>100)$ are measures ofacceptable MCMC mixing.102
33 MCMC diagnostics for the ln-scale terminal year survey MMB from the "small con-stant" model. Top row: trace plot; center row: autocorrelation plot; bottom row:histogram (left) and estimated posterior density with median (vertical line) and $80 \%$confidence interval (shading). rHat ( $<1.05$ ) and ESS ( $>100$ ) are measures of accept-able MCMC mixing.103

34 MCMC diagnostics for the terminal year survey MMB from the "zeros as NAs" model. Top row: trace plot; center row: autocorrelation plot; bottom row: histogram (left) and estimated posterior density with median (vertical line) and $80 \%$ confidence interval (shading). rHat ( $<1.05$ ) and ESS ( $>100$ ) are measures of acceptable MCMC mixing.
35 MCMC diagnostics for the terminal year survey MMB from the "small constant" model. Top row: trace plot; center row: autocorrelation plot; bottom row: histogram (left) and estimated posterior density with median (vertical line) and $80 \%$ confidence interval (shading). rHat ( $<1.05$ ) and ESS ( $>100$ ) are measures of acceptable MCMC mixing.
36 Results for the random walk model fits to mature survey biomass. Design-based estimates: points and error bars; last assessment: red line + red shading; current assessment: indicated colored lines + shading. Upper plot: arithmetic scale; lower plot: log-scale. Confidence intervals are $80 \%$.106

37 Results for the random walk model fits to mature survey biomass, showing recent time period. Design-based estimates: points and error bars (to 700 t ); last assessment: red line + red shading; current assessment: indicated colored lines + shading. Upper plot: arithmetic scale; lower plot: log-scale. Confidence intervals are 80\%. . . 107
38 One-step-ahead (OSA) residual diagnostic plots for the "zeros as NAs" random walk model. Upper left: OSA residuals vs. year; Upper right: OSA residuals vs. fitted values; Lower left: histogram and kernel density of the OSA residuals; Lower right: qqplot for the OSA residuals;
39 One-step-ahead (OSA) residual diagnostic plots for the "small constant" random walk model. Upper left: OSA residuals vs. year; Upper right: OSA residuals vs. fitted values; Lower left: histogram and kernel density of the OSA residuals; Lower right: qqplot for the OSA residuals; 109
40 Estimated MMB-at-mating. Upper plot: full time series. Lower plot: detail for 2005/06+. Dotted line is estimated time series from last assesment
41 Time frame and time series to determine the Tier $4 B_{M S Y}$. Line and points: MMB-at-mating time series. Grey fill: time frame used for averaging to determine $B_{M S Y}$. Dotted line: $B_{M S Y}$.
$42 \quad F_{O F L}$ Control Rule for Tier 4 stocks under Amendment 24 to the BSAI King and Tanner Crabs fshery management plan. Directed fshing mortality is set to 0 below ( $\beta=0.25$ ).

Figure 1. Distribution of blue king crab, Paralithodesplatypus, in Alaskan waters.

Figure 2. Map of the ADF\&G King Crab Registration Area Q (Bering Sea), showing (among others) the Pribilof District, which constitutes the stock boundary for PIBKC. The figure also indicates NMFS EBS Shelf survey grid (squares and circles), the original area used to calculate survey biomass and fishery catch data (shded in grey) in the Pribilof District, and the additional 20 nm strip (red dotted line) added in 2013.

Figure 3. The shaded area shows the Pribilof Islands Habitat Conservation Zone (PIHCZ). Trawl fishing is prohibited year-round in this zone (as of 1995), as is pot fishing for Pacific cod (as of 2015). Also shown is a portion of the NMFS annual EBS bottom trawl survey grid (squares and circles).

Figure 4. Retained catch and discard mortality, in t , for PIBKC in the crab fisheries. A discard mortality rate of 0.2 was used to convert bycatch biomass to mortality. The lower plot shows discard mortality in the crab fisheries on an expanded $y$-axis scale to show annual details.

Figure 5. Upper plot: Bycatch of PIBKC in the groundfish fisheries since 1991/92 by gear type (no mortality applied). Lower plot: Discard mortality of PIBKC in the groundfish fisheries since 1991/92 by gear type. Gear-specific discard mortality rates of 0.2 and 0.8 were applied to bycatch from fixed and trawl gear, respectively

Figure 6. Upper plot: Bycatch of PIBKC in the groundfish fisheries since 2009/10 by gear type (no mortality applied). Lower plot: Discard mortality of PIBKC in the groundfish fisheries since 2009/10 by gear type. Gear-specific discard mortality rates of 0.2 and 0.8 were applied to bycatch from fixed and trawl gear, respectively

Figure 7. Upper plot: Bycatch of PIBKC in the groundfish fisheries since 2009/10 by target type (no mortality applied). Lower plot: Discard mortality of PIBKC in the groundfish fisheries since 2009/10 by target type. Gear-specific discard mortality rates of 0.2 and 0.8 were applied to bycatch from fixed and trawl gear, respectively

Figure 8. Estimated bycatch of PIBKC in the groundfish trawl gear fisheries by ADF\&G stat area, expanded from groundfish observer reports. Red line: boundary of the PIHCZ.

Figure 9. Estimated bycatch of PIBKC in the groundfish fixed gear fisheries by ADF\&G stat area, expanded from groundfish observer reports. Red line: boundary of the PIHCZ.

Figure 10. NMFS EBS Shelf Survey stations in the Pribilof District (large dots), the survey station grid (thin black lines), and the Pribilof Islands Habitat Conservation Zone (orange outline).

Figure 29. Decadal-average biomass CPUE (t/sq-nmi) by for female PIBKC in the NMFS EBS trawl survey.

Figure 30. MCMC diagnostics for the ln-scale process error parameter from the "zeros as NAs" model. Top row: trace plot; center row: autocorrelation plot; bottom row: histogram (left) and estimated posterior density with median (vertical line) and $80 \%$ confidence interval (shading). rHat ( $<1.05$ ) and ESS $(>100)$ are measures of acceptable MCMC mixing.

Figure 31. MCMC diagnostics for the $\ln$-scale process error parameter from the "small constant" model. Top row: trace plot; center row: autocorrelation plot; bottom row: histogram (left) and estimated posterior density with median (vertical line) and $80 \%$ confidence interval (shading). rHat ( $<1.05$ ) and ESS $(>100)$ are measures of acceptable MCMC mixing.

Figure 32. MCMC diagnostics for the ln-scale terminal year survey MMB from the "zeros as NAs" model. Top row: trace plot; center row: autocorrelation plot; bottom row: histogram (left) and estimated posterior density with median (vertical line) and $80 \%$ confidence interval (shading). rHat ( $<1.05$ ) and ESS ( $>100$ ) are measures of acceptable MCMC mixing.

Figure 33. MCMC diagnostics for the $\ln$-scale terminal year survey MMB from the "small constant" model. Top row: trace plot; center row: autocorrelation plot; bottom row: histogram (left) and estimated posterior density with median (vertical line) and $80 \%$ confidence interval (shading). rHat ( $<1.05$ ) and ESS ( $>100$ ) are measures of acceptable MCMC mixing.

Figure 34. MCMC diagnostics for the terminal year survey MMB from the "zeros as NAs" model. Top row: trace plot; center row: autocorrelation plot; bottom row: histogram (left) and estimated posterior density with median (vertical line) and $80 \%$ confidence interval (shading). rHat ( $<1.05$ ) and ESS ( $>100$ ) are measures of acceptable MCMC mixing.

Figure 35. MCMC diagnostics for the terminal year survey MMB from the "small constant" model. Top row: trace plot; center row: autocorrelation plot; bottom row: histogram (left) and estimated posterior density with median (vertical line) and $80 \%$ confidence interval (shading). rHat ( $<1.05$ ) and ESS $(>100)$ are measures of acceptable MCMC mixing.

Figure 36. Results for the random walk model fits to mature survey biomass. Design-based estimates: points and error bars; last assessment: red line + red shading; current assessment: indicated colored lines + shading. Upper plot: arithmetic scale; lower plot: $\log$-scale. Confidence intervals are $80 \%$.

Figure 37. Results for the random walk model fits to mature survey biomass, showing recent time period. Design-based estimates: points and error bars (to 700 t ); last assessment: red line + red shading; current assessment: indicated colored lines + shading. Upper plot: arithmetic scale; lower plot: log-scale. Confidence intervals are $80 \%$.

Figure 38. One-step-ahead (OSA) residual diagnostic plots for the "zeros as NAs" random walk model. Upper left: OSA residuals vs. year; Upper right: OSA residuals vs. fitted values; Lower left: histogram and kernel density of the OSA residuals; Lower right: qqplot for the OSA residuals;

Figure 39. One-step-ahead (OSA) residual diagnostic plots for the "small constant" random walk model. Upper left: OSA residuals vs. year; Upper right: OSA residuals vs. fitted values; Lower left: histogram and kernel density of the OSA residuals; Lower right: qqplot for the OSA residuals;

Figure 40. Estimated MMB-at-mating. Upper plot: full time series. Lower plot: detail for 2005/06+. Dotted line is estimated time series from last assesment.

Figure 41. Time frame and time series to determine the Tier $4 B_{M S Y}$. Line and points:
MMB-at-mating time series. Grey fill: time frame used for averaging to determine $B_{M S Y}$. Dotted line: $B_{M S Y}$.

Figure 42. $F_{O F L}$ Control Rule for Tier 4 stocks under Amendment 24 to the BSAI King and Tanner Crabs fshery management plan. Directed fshing mortality is set to 0 below ( $\beta$ $=0.25$ ).
