

SECRETARIAL REVIEW

Environmental Assessment/ Regulatory Impact Review/ Initial Regulatory Flexibility Analysis for
Amendment 89 to the Fishery Management Plan for Groundfish of the Gulf of Alaska

Area Closures for Tanner Crab (*Chionoecetes bairdi*) Protection in Gulf of Alaska Groundfish Fisheries

Abstract: This EA/RIR/IRFA analyzes the impacts of four alternatives to close specific areas of the Central Gulf of Alaska Regulatory Area (Central GOA) to the use of trawl gear and pot gear or as a suboption, in lieu of a closure to require additional observer coverage in these areas. Based on the Council's recommendation, NMFS determined that increased observer coverage in specific areas of the Central GOA would interfere with the goals and objectives of the restructured observer program and is not necessary. The intent to improve Tanner crab bycatch information is addressed in the restructured observer program, which was implemented in 2013. The Council's preferred alternative is to close a portion of Marmot Bay northeast of Kodiak Island to the use of trawl gear, except for the use of pelagic trawl gear to target pollock. The Council's preferred alternative for the Marmot Bay Protection Area trawl closure will be combined with the Council's preferred alternative requiring modified nonpelagic trawl gear to be used when targeting flatfish in Central Gulf of Alaska Regulatory Area to form a suite of management measures for the protection and conservation of Tanner crab and reduce the potential for adverse impacts by nonpelagic gear on benthic habitat.

May 2013

Executive Summary

ES.1 Introduction

This document analyzes proposed area closures to protect Tanner crab (*C. bairdi*) around Kodiak Island. Included in the alternatives are options to apply the closures year round or seasonally, and to pot and/or trawl gear types. Additionally, the analysis also examines exempting some vessels from the area closures if they meet specific conditions such as using approved gear modifications, or an observer coverage requirement.

ES.2 Purpose and Need

The purpose of this action is to provide additional protection to Gulf of Alaska (GOA) Tanner crab from the potential adverse effects of groundfish fisheries. This action is necessary to protect Tanner crab stocks in the Gulf of Alaska. This would be achieved by closing areas around Kodiak Island that are important to the Tanner crab stocks. Areas would be closed to some or all groundfish fishing, depending on the vessel's gear type or gear configuration. The North Pacific fishery Management Council (Council) also examined several alternatives for increased observer coverage requirements in order to improve estimates of prohibited species catch (PSC) in the closed area, as a basis for future management action as necessary. In October 2010, the Council recommended that PSC catch estimation be improved either by this action or by the restructured observer program, if the restructuring is not unduly delayed. The restructured observer program was implemented in 2013 (77 FR 70062, November 21, 2012). Based on the Council's intent to improve Tanner crab bycatch information through this action or through the implementation of the restructured observer program, NMFS, in consultation with the Council, determined that increased observer coverage requirements under this action are not necessary. The restructured observer program is anticipated to meet the Council's desire for more accurate and reliable information on fishing activities. Details of the restructured observer program are available in the proposed rule (77 FR 23326, April 18, 2012). The restructured observer program would improve the quality of fisheries data, including the catch information for Tanner crab in the groundfish fisheries. Vessels under the restructured observer program would be either fully or partially observed. A randomized system for the assignment of observer coverage throughout the GOA for partially observed vessels would be used to reduce potential bias in the observer data. Selecting locations for increased observer coverage would reduce the ability to randomize observer assignments and therefore potentially bias observer data. This would not meet the Council's intent to improve the quality of observer information under Amendment 76. For these reasons, increased observer coverage in specific areas under Amendment 89 will not be pursued.

The Council formulated a problem statement in October 2009, to initiate this analysis, and revised it in April and October 2010:

Tanner crab are a prohibited species in the Gulf of Alaska (GOA) groundfish fisheries. Directed fisheries for Tanner crab in the GOA are fully allocated under the current limited entry system. No specific conservation measures exist in the GOA to address adverse interactions with Tanner crab by trawl and fixed gear sectors targeting groundfish and low observer coverage in GOA groundfish fisheries limits confidence in the assessment of Tanner crab PSC [prohibited species catch] in those fisheries, and a greater level of observer coverage in the appropriate areas may provide the Council with a higher level of confidence in the assessment of any PSC occurring in the designated areas as a basis for future management actions as necessary. Trawl sweep modifications

have been effective in reducing unobserved PSC mortality of Tanner crab in the Bering Sea, and similar effects may be realized in the Gulf of Alaska if modified trawl sweeps are employed in those groundfish fisheries.

The Council's intent in its problem statement was to investigate the practicality of using modified nonpelagic trawl gear, similar to the requirements in the Bering Sea, as a trailing amendment to comprise a suite of management measures to protect Tanner crab. In April 2012, the Council recommended vessels using nonpelagic trawl gear to target flatfish in the Central GOA to use approved modified gear to reduce the potential adverse effects of nonpelagic trawl gear on benthic habitat and to reduce unobserved Tanner crab injury and mortality. In the GOA, fishing for flatfish includes vessels targeting shallow-water flatfish, deep-water flatfish, arrowtooth flounder, rex sole, and flathead sole. These species and species groups are defined in the annual groundfish harvest specification proposed and final rules each year.

Studies in the Bering Sea (BS) have shown that elevating the trawl sweep can reduce trawl sweep impacts effects on *C. bairdi*, *C. opilio* and red king crabs by reducing the unobserved mortality of these species. In addition, elevating the trawl sweep can reduce impacts on benthic organisms, such as basketstars and sea whips. Further research was conducted in 2011 in the GOA to identify the appropriate standards for the elevated trawl sweeps to meet the Council's desired performance standard, and to identify and resolve any implementation issues. Field testing of the modified gear demonstrated that the elevated trawl sweeps can meet the standards adopted for the Bering Sea subarea (BS) flatfish fishery (75 FR 61642, October 6, 2010) and can be used in the Central GOA flatfish fishery. For rulemaking efficiency, the revisions to the regulations for the trawl sweep modification and area closures will be combined as one action. A separate EA/RIR/IRFA was developed to analyze the effects of the alternatives for the trawl sweep modifications, which is available at www.alaskafisheries.noaa.gov/cm/analyses.

ES.3 Alternatives

The alternatives evaluated in this analysis were adopted by the Council in October 2009, and modified during initial review in April 2010. The Council's preferred alternative, determined in October 2010, follows.

Alternative 1: Status Quo – No action

Alternative 2: Close the areas specified below to pot and trawl groundfish fisheries.

Component 1: Area definition

ADF&G Northeast Section

Option 1: Statistical Area 525807 and the area east of Statistical Area 525807 north of 58 degrees latitude, south of 58 degrees 15 min. latitude and west of 151 degrees 30 min. longitude.

Option 2: Chiniak Gully (Four corners at 152°19'34" W x 57°49'24" N by 57°29' N x 151°20' W by 57°20' N x 151°20' W by 57° x 152°9'20" W), excluding State waters

ADF&G Eastside Section

Option 3: Statistical Area 525702

ADF&G Southeast Section

Option 4: Statistical Area 525630

Component 2: Closure timing

Option 1: Year round

Suboption 1: trawl gear

Suboption 2: pot gear

Suboption 3: Vessels using approved, modified gear would be exempt from closures (e.g., trawl sweep modifications or pot escape mechanisms).

Suboption 4: Vessels using pelagic trawl gear would be exempt from closures

Suboption 5: Vessels using pelagic trawl gear to directed fish for pollock would be exempt from the closures

Option 2: Seasonally (January 1 – July 31)

Suboption 1: trawl gear

Suboption 2: pot gear

Suboption 3: Vessels using approved, modified gear would be exempt from closures (e.g., trawl sweep modifications or pot escape mechanisms).

Suboption 4: Vessels using pelagic trawl gear would be exempt from closures

Suboption 5: Vessels using pelagic trawl gear to directed fish for pollock would be exempt from the closures

Alternative 3: In order to fish in the areas specified below, require 100 percent observer coverage on all trawl groundfish vessels and 30 percent observer coverage on all pot groundfish vessels less than 125 feet. Note, fishing days and observer coverage in these areas would be separate from, and not count towards, meeting a groundfish pot vessel's overall 30 percent groundfish observer coverage requirement.

Area definition

ADF&G Northeast Section

Option 1: Statistical Area 525807 and the area east of Statistical Area 525807 north of 58 degrees latitude, south of 58 degrees 15 min. latitude and west of 151 degrees 30 min. longitude.

Option 2: Chiniak Gully (Four corners at 152°19'34" W x 57°49'24" N by 57°29' N x 151°20' W by 57°20' N x 151°20' W by 57° x 152°9'20' W), excluding State waters

ADF&G Eastside Section

Option 3: Statistical Area 525702

ADF&G Southeast Section

Option 4: Statistical Area 525630

Note, the options and suboptions under Alternatives 2 and 3 are not intended to be mutually exclusive, and may be applied in combination. Also, in April 2010, the Council clarified that at final action, they may select closure areas that are smaller than the areas described in the four options under the 'area definition' component.

Figure 1 Area closures around Kodiak Island considered in Alternatives 2 and 3

Council's preferred alternative

In October 2010, the Council adopted the following recommendations as their preferred alternative for this action. The recommendations combine elements of both Alternatives 2 and 3.

Close the area specified below to trawl groundfish fisheries, and require observer coverage for the pot groundfish fishery.

Area definition:

ADF&G Northeast Section: Statistical Area 525807 and the area east of Statistical Area 525807 north of 58 degrees latitude, south of 58 degrees 15 min. latitude and west of the longitude line extending north from the eastern boundary of the Type 1 red king crab closure area (Figure 4).

Closure timing: Year round

Vessels using pelagic trawl gear to directed fish for pollock would be exempt from the closures

Observer coverage for pot groundfish fishery

In order to fish in the area, require 30 percent observer coverage on all pot groundfish vessels less than 125 feet. Note, fishing days and observer coverage in these areas would be separate from, and not count towards, meeting a vessel's overall 30 percent groundfish observer coverage requirement. The Council encourages the agency to incorporate, to the extent achievable, in the new fee-based observer program, an observer deployment strategy that ensures adequate coverage to establish statistically robust observations in the area described.

Require observer coverage for the nonpelagic trawl and pot groundfish fisheries in the areas specified below

In order to fish in the areas specified below, require 100 percent observer coverage on all nonpelagic trawl groundfish vessels and 30 percent observer coverage on all pot groundfish vessels less than 125 feet. Note, fishing days and observer coverage in these areas would be separate from, and not count towards, meeting a vessel's overall 30 percent groundfish observer coverage requirement. The Council encourages the agency to incorporate, to the extent achievable, in the new fee-based observer program, an observer deployment strategy that ensures adequate coverage to establish statistically robust observations in the areas described below.

Areas:

- *ADF&G Northeast Section: Chiniak Gully* (Four corners at 152°19'34" W x 57°49'24" N by 57°29' N x 151°20' W by 57°20' N x 151°20' W by 57° x 152°9'20" W), excluding State waters (Figure 4).
- *ADF&G Eastside Section: Statistical Area 525702* (Figure 4).

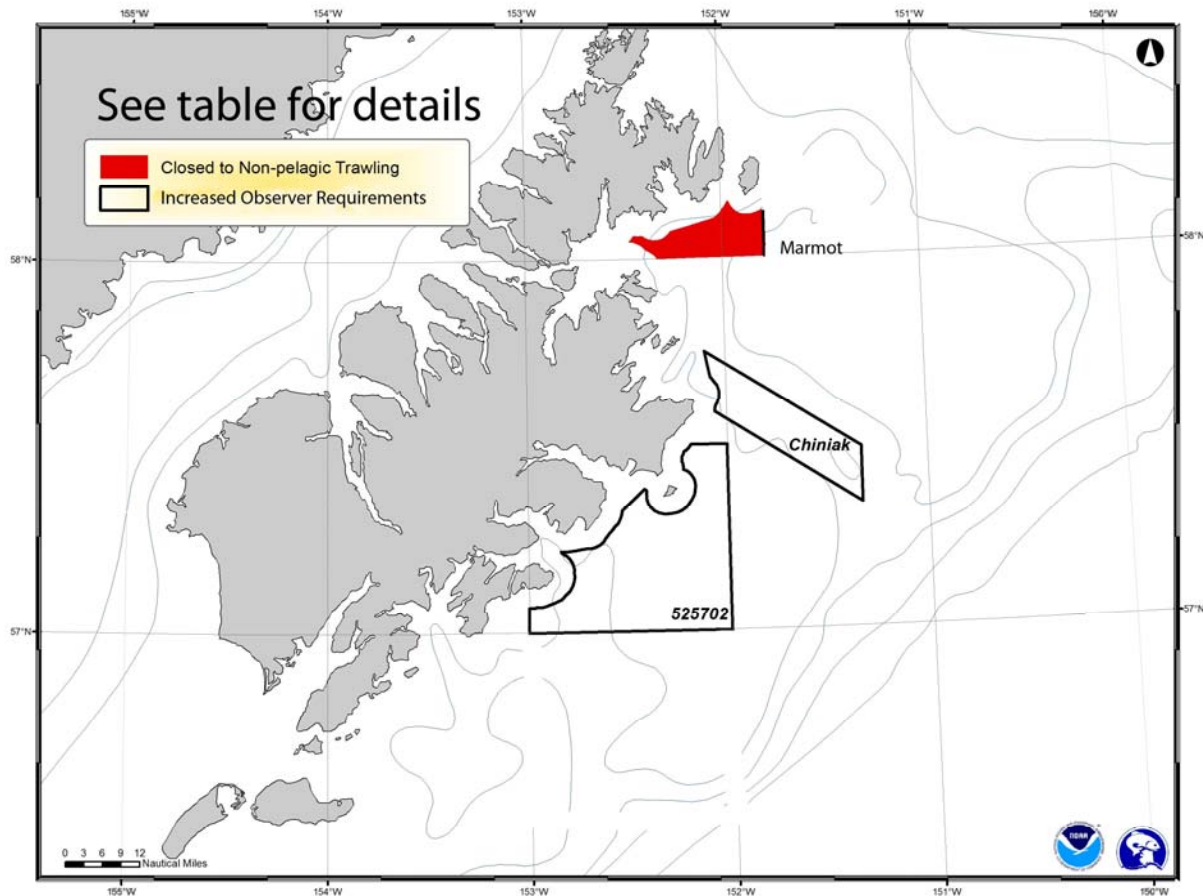

Develop a trailing amendment to require trawl vessels to use approved modified gear, such as trawl sweep modifications, in the Central GOA nonpelagic trawl fishery. Council staff prepared an EA/RIR/IRFA to examine the efficacy of requiring the use of modified nonpelagic trawl gear and as its preferred alternative recommended that modified nonpelagic trawl gear, as adopted for the Bering Sea be required by vessels using nonpelagic trawl gear to target flatfish in the Central Gulf of Alaska Regulatory Area to reduce unobserved injury and mortality of crab and to reduce the footprint on benthic habitat by nonpelagic trawl gear.

In April 2012, the Council recommended that vessels using nonpelagic trawl gear to target flatfish in the Central GOA use approved modified gear to reduce the potential adverse effects of nonpelagic trawl gear on benthic habitat and to reduce unobserved Tanner crab injury and mortality. In the GOA, fishing for flatfish includes vessels targeting shallow-water flatfish, deep-water flatfish, arrowtooth flounder, rex sole, and flathead sole. These species and species groups are defined in the annual groundfish harvest specification proposed and final rules each year.

Studies in the Bering Sea (BS) have shown that elevating the trawl sweep can reduce trawl sweep impacts on *C. bairdi*, *C. opilio* and red king crabs by reducing the unobserved mortality of these species. In addition, elevating the trawl sweep can reduce impacts on benthic organisms, such as basketstars and sea whips. Further research was conducted in 2011 in the GOA to identify the appropriate standards for the elevated trawl sweeps, to meet the Council's desired performance standard, and to identify and resolve any implementation issues. Field testing of the modified gear demonstrated that the elevated trawl sweeps can meet the standards adopted for the Bering Sea subarea (BS) flatfish fishery (75 FR 61642, October 6, 2010) and can be used in the Central GOA flatfish fishery.

Based on the Council's recommendation to implement improved observer information either through this action or the restructured observer program, NMFS, in consultation with Council, determined that the observer options in the Tanner crab protection measures action are not necessary to achieve the Council's goal to improve Tanner crab PSC data, and they will not be part of the final action. Amendment 76 to the Fishery Management Plan for Groundfish of the GOA was approved on June 7, 2012 (77 FR 15079, March 14, 2012). This amendment provides the restructured Observer Program that will improve overall catch data information for the GOA. Under the deployment plan, it is not possible to establish discrete areas with vessel specific observer requirements and maintain the random selection necessary to ensure statistically robust observations throughout the GOA. Because overall observer data will be improved, the restructured Observer Program will meet the Council's objective to have better information on Tanner crab PSC not only in the areas described in the option but also across the GOA. The comment period on

the proposed rule closed (77 FR 23326, April 18, 2012), and the program was implemented in 2013 (77 FR 70062, November 21, 2012).

	Trawl	Pot
Marmot Bay	Closed (vessels using pelagic trawl gear to fish for pollock are exempt)	Closed to pot gear unless 30 percent observer coverage
Chiniak Gully	Closed to nonpelagic trawl gear unless 100 percent observer coverage	
ADFG statistical area 525702		

Figure 2 Areas established around Kodiak under the preferred alternative, in which nonpelagic trawl gear is prohibited, or nonpelagic trawl and pot vessels may only fish if they carry observer coverage

ES.4 Impacts of the Alternatives

The alternatives were analyzed for their impacts on crab, groundfish and other fish species, marine mammals and seabirds, habitat, and the ecosystem, and for their economic and socio-economic impacts. The impacts on the socio-economic environment are analyzed in the Regulatory Impact Review (Section 6) and the Initial Regulatory Flexibility Analysis (Section 7) and are summarized in the following section.

The proportion of the surveyed abundance of Tanner crab around Kodiak which is taken as PSC in the groundfish fisheries represents approximately 0.2 percent of the total surveyed abundance of crab. In the

Eastside Section, which is identified as an important area for Tanner crab, groundfish PSC represents a maximum of 0.3 percent of the Eastside surveyed abundance of Tanner crab, average over 2003 through 2009. Consequently, groundfish PSC impacts on the sustainability of Tanner crab in the Kodiak District under the status quo, Alternative 1, are considered as adverse, but are not likely to be significant to the sustainability of the crab population.

Alternative 2, closing the proposed areas to groundfish fishing, would benefit crab stocks by reducing a source of mortality. Benefits to crab would be greatest by closing the areas to nonpelagic trawl fishing, as this gear type is observed to catch most of the crab in these areas. While pot vessels also contribute to the overall Tanner crab PSC in reporting area 630, and to some extent in the proposed area closures, observed crab PSC in the pot fisheries occurred predominantly elsewhere in reporting area 630. Pelagic trawl and hook-and-line vessels account for very little crab PSC, and closing the proposed areas to these gear types would provide little benefit to the crab stocks.

The impacts of suboption 3 under Alternative 2, which would exempt vessels from the closures if using approved gear modifications, are difficult to assess as proposed gear modifications have not been tested in the GOA. To the extent that they reduce unobserved mortality of crab, or reduce PSC, they are likely to be beneficial to crab stocks. Alternative 3, which exempts vessels from the closures if they have 100 percent observer coverage, does not provide any benefit to crab stocks over the status quo, for those vessels that take advantage of the exemption.

The Council's preferred alternative is a combination of Alternatives 2 and 3. The preferred alternative closes the Marmot Bay area (statistical area 525807) year-round to fishing with trawl gear except for directed fishing for pollock with pelagic trawl gear. The Marmot Bay area had the highest observed PSC mortality rate of Tanner crab for nonpelagic trawl vessels. The nonpelagic trawl gear sectors observed Tanner crab PSC in the area accounted for an average of 4 percent of the total observed Tanner crab PSC in the groundfish fisheries for 2001 through 2009. The area closure to trawl gear will reduce PSC of Tanner crab, although only by a small percentage of the total Tanner crab PSC in groundfish fisheries.

The impact of the alternatives on other resource categories analyzed in the EA, including groundfish and other fish species, marine mammals, seabirds, habitat, and the ecosystem, are not expected to be significant. The timing, general location, and overall level of fishing effort in the GOA groundfish fisheries is not expected to change, as the proposed area closures are small and fishing will likely continue to occur in neighboring areas.

ES.5 Management and enforcement considerations

The boundaries of the proposed closure areas under Alternatives 2, 3, the Council's Preferred Alternative are defined by existing ADF&G statistical areas and by polygons defined by latitude and longitude coordinates. Closure areas defined in this manner are easier for both the regulated industry to understand and comply with, as well as enforcement entities to patrol and enforce. The proposed closure areas present no noteworthy enforcement challenges.

Proposed modified gear requirements under Alternative 2, Suboption 3, such as trawl sweep modifications or pot escapement mechanisms, require a detailed description in regulations of the specific gear modification that would be required to qualify for exemption of the area closures. Such specifications have been discussed in general in this analysis, but no specific gear modifications have been described or widely tested for efficacy in protection of Tanner crab in the GOA fisheries. Therefore, Alternative 2, Suboption 3 was not included in the preferred alternative as a specific recommended regulatory amendment at this time, and is instead being developed as a trailing amendment.

Suboptions 4 and 5 would exempt vessels using pelagic trawl gear from the proposed area closures. There are several areas around Kodiak Island that already are closed to nonpelagic (bottom) trawling. These closure areas overlap with some of the closure areas proposed under Alternative 2, although not with the closure that is proposed under the Preferred Alternative. These existing closure areas are regulated through a prohibition against having nonpelagic trawl gear onboard the vessel, as well as a “trawl gear performance standard”, which specifies that it is unlawful to possess aboard a vessel, at any point in time, 20 or more crab of any species, with a carapace width of more than 1.5 inches, also applies for vessels directed fishing for pollock. Enforcement of this standard on any vessel (observed or unobserved) is difficult, and it is virtually impossible to monitor and enforce on unobserved vessels.

Alternative 3 would allow fishing in the proposed closure areas by vessels using trawl gear only if they carry an observer 100 percent of the days they conducted directed fishing for groundfish in these areas. All vessels using pot gear to directed fish for groundfish would be required to have 30 percent observer coverage. In addition, observer coverage for fishing inside these closure areas would be separate from, and not count towards meeting a pot vessel’s 30 percent observer coverage requirements that applied for fishing outside of these closure areas. This last provision was added to the alternative to address the concern NMFS identified in the initial review draft that increased observer coverage requirements inside the proposed closure areas could decrease the observer data available from fishing outside of the closure areas. While this provision addresses that concern, the other concern identified in the initial review draft about the extrapolation of observer data to generate PSC estimates remains.

NMFS uses observer data and extrapolates PSC sampled on observed trips to similar unobserved trips in the larger federal reporting area (by processing sector, week ending date, target fishery, gear, and federal reporting area). NMFS does not create separate PSC estimates for each ADF&G state statistical area or for catcher vessels fishing inside and outside of closure areas, such as those proposed in this action. It is not known whether data collected from the proposed closure areas would be representative of fishing over the entire reporting area. However, through ongoing work NMFS is working to improve the estimation process in concert with the observer restructuring efforts. The restructured program would enable NMFS to define estimation strata and randomly select trips at a consistent rate within them. Action to increase observer coverage in this one GOA area without modifications to the NMFS catch estimation process could result in estimates which are biased by data from this specific area. Thus, NMFS would need to make changes to the current estimation process to accommodate this change in coverage. Likely NMFS would need to handle estimation for this specific area discrete from other areas in the GOA. Modifications to the catch estimation process would be complex and expensive, and would compete with other priorities for additions and improvements to NMFS’s catch accounting system.

Some vessels less than 60 feet LOA may have fished in the proposed closure areas in the past. Under Alternative 3, any vessels of this size class would be required to carry observers for at least some of the fishing inside the proposed closure areas (unless they didn’t meet the minimum threshold for observer coverage of 3 days per quarter). Although some vessel operators may choose to fish outside the closure areas, rather than incur the cost of the required observer coverage, some of these vessels may seek observer coverage. They would be required to comply with existing safety and all other vessel requirements in 50 CFR part 679.50.

If the Council recommends increased observer coverage for vessels fishing with the GOA Tanner crab protection areas under Alternative 3, this would add a third special area with 100 percent observer coverage requirements to NMFS’s current regulations. Existing areas are the Nearshore Bristol Bay Trawl Closure Area and the Red King Crab Savings Area, both in the BSAI management area. These specific requirements for 100 percent observer coverage within special areas currently are not included in the categories that would require ≥ 100 percent observer coverage under the observer restructuring

alternatives. Therefore, if the Council recommends an observer restructuring alternative that places vessels in the <100 percent observer coverage category in a management area under a sampling plan, NMFS would remove the increased observer coverage for the “special areas” in the relevant management area. Vessels in the <100 percent observer coverage category would be subject to assignment of observer coverage under a sampling plan as described in the observer restructuring analysis.

The Council’s current alternatives for restructuring the observer program could accommodate continuation of 100 percent observer coverage requirements for all vessels within these special areas. Vessels that are in the <100 percent coverage category would pay an exvessel value based fee for observers, and these vessels would be subject to an annual sampling plan developed by NMFS. Should vessels choose to fish in the special areas, the sample design could require that they carry observers 100 percent of the time they are directed fishing for groundfish in these areas. Thus, even though many of the affected vessels would not have 100 percent coverage any other time or in any other area, the observer restructuring action allows for flexibility in determining coverage on vessels in the <100 percent coverage category. If a group of vessels is determined to need 100 percent coverage at specific times of the year, seasons, or areas, NMFS could direct observer deployment to accommodate those needs. The fee paid by those vessels would not change, but the coverage amount could be modified to account for those circumstances; this flexibility is part of the impetus of restructuring. This accommodation in the sampling plan is not currently described in the observer restructuring analysis, as that level of detail by sector was not deemed necessary. Establishing special areas of 100 percent observer coverage would significantly complicate the current sampling plan and necessarily reduce the amount of coverage days available for other fisheries and management priorities in the GOA. The vessel selection plan currently included in the observer restructuring analysis does not assign observer coverage based on what a vessels intends to do. Instead, it takes parameters such as vessel length and gear type, which are known in advance, and assigns random coverage of trips based on a pre-determined coverage rate. Vessels would call in, prior to trips, and be selected for coverage or not regardless of where they planned to fish.

ES.6 Regulatory Impact Review

The Regulatory Impact Review is in Section 6 of this document, and describes the economic impacts of the alternatives. Under the closures proposed under Alternatives 2 and 3, groundfish vessels that are subject to the closures will be required to forego fishing in the proposed areas. The impact on these vessels will be proportional to the extent that they rely on the area for target fishing, as well as the degree to which displaced catch can be made up in remaining open areas.

Based on observer data, the nonpelagic trawl fishery will be most severely impacted by the area closures, especially the flatfish fisheries. An estimated 65 to 70 percent of groundfish caught in the pollock target fishery occurs in the Chiniak and 525702 closure areas; 50 to 60 percent of groundfish in the arrowtooth flounder and flathead sole target fisheries occurs in 525702 and 525630; 50 percent of shallow-water flatfish catches occur in 525702; and 60 to 70 percent of the rex sole target fishing occurs in 525630. For arrowtooth flounder and flathead sole targets, there are areas outside of the proposed closures where a concentration of catch in those targets occurs, however for the shallow-water flatfish target fishery, there are few areas outside of the proposed area closures where significant catch have occurred. Therefore particularly for shallow water flatfish, it may be difficult to fully harvest the TAC outside the proposed area closures. There are several catcher vessels that derive over 20 percent of their exvessel revenue from flatfish from the 525702 and 525630, and these vessels would likely be more severely impacted than others by the proposed closures. To the extent that flatfish TACs cannot be fully harvested as a result of this alternative, there may also be impacts on the community of Kodiak and processing facilities.

For pelagic trawlers, the biggest impact would result from closing 525702, where the western and central portions of the statistical area are important for pollock trawling. Approximately 25 percent of the groundfish catch in the pollock pelagic trawl target fishery occurred within the Marmot, Chiniak, and 525702 closures, on average between 2007 and 2009. However, the pelagic trawl pollock fishery is conducted in other areas within reporting area 630, which would remain open to fishing.

For pot vessels, the proposed area closures are expected to have a smaller impact on groundfish fishing because, according to observer data, these areas are not as heavily fished as other parts of reporting area 630. However, there appear to be a higher proportion of pot vessels using the proposed area closures that are unobserved, so observer data may be less reliable for this gear type. Fish ticket data identify that an average of 42 percent of exvessel revenue from pot vessels came from the combined 525702 and 525630 statistical areas.

Under Option 2, the seasonal closure, adverse impacts from the area closures on groundfish fishermen would be reduced compared to Option 1, as vessels could fish in the areas for portions of the year.

Alternative 3 would increase costs to the owners of any vessel that continued to fish in the closure areas that are not already required to have 100 percent or greater observer coverage. The category of vessels that could incur increased costs are: (1) vessels less than 60 feet LOA currently required to have no observer coverage, and (2) vessels currently required to have only 30 percent observer coverage. Under Alternative 3, the estimated total increase in costs for between 60 feet and 125 feet trawl catcher vessels under Alternative 3 is the full cost of 100 percent observer coverage inside these areas (\$558,882 or an average of \$17,465 per vessel). The estimated increase in cost under Alternative 3 for vessels using pelagic trawl gear would total of \$30,744 or about \$900 per vessel. Because most of the 37 vessels using trawl gear in these areas in 2009 used both nonpelagic and pelagic trawl gear, the total cost of the increased observer coverage requirements for many trawl vessels between 60 feet and 125 feet LOA would be the sum of the cost estimates for nonpelagic and pelagic trawl gear (\$589,626 or an average of \$15,936 for the 37 vessels between 60 feet and 125 feet LOA using trawl gear). For vessels less than 60 feet using pot gear, the total cost for that observer coverage is estimated at \$33,764 (average per vessel of \$2,814). For pot catcher vessels between 60 feet and 125 feet, the total cost is estimated to be \$22,948, an average of \$2,086 per vessel. NMFS estimates that each day of additional observer coverage costs the agency \$130. Based on 2009 data, the agency may expect an increase in cost of approximately \$277,000, a cost that is not currently identified in NMFS's budget. However, under the restructured Observer Program scheduled for implementation at the beginning of 2013, a fee-structured program for vessels which do not require 100 percent observer coverage, would meet these costs.

ES.7 Initial Regulatory Flexibility Analysis

This action could directly regulate all pot and trawl vessels participating in Federal groundfish fisheries around Kodiak Island in the Central Gulf of Alaska. From 2003 through 2009, there were 74 nonpelagic trawl vessels, 53 pelagic trawl vessels, and 129 groundfish pot vessels with reported Tanner crab PSC, participating in one or multiple years in the groundfish fisheries in reporting area 630. Of the vessels fishing in reporting area 630, from 2003 through 2009, with reported Tanner crab PSC, 26 nonpelagic trawl vessels, 12 pelagic trawl vessels, and 97 pot vessels are considered small for RFA purposes.

ES.8 Organization of the document

There are four required components of an environmental assessment. The need for the proposal is described in Section 1, and the alternatives in Section 2, Section 3 discusses the affected environment,

Section 4 discusses the environmental impacts of the proposed action and alternatives; finally, a list of agencies and persons consulted is included in Section 10.2.

Management and enforcement considerations are addressed in Section 5. A Regulatory Impact Review (Section 6) discusses economic impacts of the action, and an Initial Regulatory Flexibility Analysis (Section 7) evaluates the impact of the action on small businesses. Sections 8 and 9 discuss the alternatives with respect to other analytical considerations.

Color figures mapping the distribution of PSC and groundfish catch are included at the end of the document, in Appendix A Color Figures.

1 Introduction and Purpose

This document analyzes proposed area closures to protect *Chionoectes bairdi* Tanner crab around Kodiak Island. Included in the alternatives are options to apply the closures year round or seasonally, and to pot and/or trawl gear types. Additionally, under some alternatives, some vessels may be exempted from the area closures, if they meet specific conditions such as using approved gear modifications, or an observer coverage requirement.

This document is an Environmental Assessment/Regulatory Impact Review/Initial Regulatory Flexibility Analysis (EA/RIR/IRFA). An EA/RIR/IRFA provides assessments of the environmental impacts of an action and its reasonable alternatives (the EA), the economic benefits and costs of the action alternatives, as well as their distribution (the RIR), and the impacts of the action on directly regulated small entities (the IRFA). This EA/RIR/IRFA addresses the statutory requirements of the MSA, the National Environmental Policy Act (NEPA), Presidential Executive Order 12866, and Regulatory Flexibility Act (RFA). An EA/RIR/IRFA is a standard document produced by the Council and the NMFS Alaska Region to provide the analytical background for decision-making.

1.1 Purpose and need

The purpose of this action is to provide additional protection to Gulf of Alaska (GOA) Tanner crab from the potential adverse effects of groundfish fisheries. This action is necessary to protect Tanner crab stocks in the Gulf of Alaska. This would be achieved by closing areas around Kodiak Island that are important to the Tanner crab stocks. Areas would be closed to some or all groundfish fishing, depending on the vessel's gear type or gear configuration. The North Pacific Fishery Management Council (Council) also examined several alternatives for increased observer coverage requirements in order to improve estimates of prohibited species catch (PSC) in the closed area, as a basis for future management action as necessary. In October 2010, the Council recommended that PSC catch estimation be improved either by this action or by the restructured observer program, if the restructuring is not unduly delayed. The restructured observer program was implemented in 2013 (77 FR 70062, November 21, 2012). Based on the Council's intent to improve Tanner crab bycatch information through this action or through the implementation of the restructured observer program, NMFS, in consultation with the Council, determined that increased observer coverage requirements under this action are not necessary. The restructured observer program is anticipated to meet the Council's desire for more accurate and reliable information on fishing activities. Details of the restructured observer program are available in the proposed rule (77 FR 23326, April 18, 2012). The restructured observer program would improve the quality of fisheries data, including the catch information for Tanner crab in the groundfish fisheries. Vessels under the restructured observer program would be either fully or partially observed. A randomized system for the assignment of observer coverage throughout the GOA for partially observed vessels would be used to reduce potential bias in the observer data. Selecting locations for increased observer coverage would reduce the ability to randomize observer assignments and therefore potentially bias observer data. This would not meet the Council's intent to improve the quality of observer information under Amendment 76. For these reasons, increased observer coverage in specific areas under Amendment 89 will not be pursued.

1.2 Council's problem statement

The Council formulated a problem statement in October 2009, to initiate this analysis, and revised it in April and October 2010:

Tanner crab are a prohibited species in the Gulf of Alaska (GOA) groundfish fisheries. Directed fisheries for Tanner crab in the GOA are fully allocated under the current limited entry system. No specific conservation measures exist in the GOA to address adverse interactions with Tanner crab by trawl and fixed gear sectors targeting groundfish and low observer coverage in GOA groundfish fisheries limits confidence in the assessment of Tanner crab PSC in those fisheries, and a greater level of observer coverage in the appropriate areas may provide the Council with a higher level of confidence in the assessment of any PSC occurring in the designated areas as a basis for future management actions as necessary. Trawl sweep modifications have been effective in reducing unobserved PSC mortality of Tanner crab in the Bering Sea, and similar effects may be realized in the Gulf of Alaska if modified trawl sweeps are employed in those groundfish fisheries.

The intent of the increased coverage is to improve Tanner crab PSC data in the GOA groundfish fisheries. On June 7, 2012, the Secretary of Commerce approved Amendment 76 to the FMP for the restructured observer program (77 FR 15019, March 14, 2012), and the final rule implementing this action is scheduled to be completed by January 1, 2013. Details of the restructured observer program are available in the proposed rule (77 FR 23326, April 18, 2012). The restructured observer program would improve the quality of fisheries data, including the catch information for Tanner crab in the groundfish fisheries. Vessels under the restructured observer program would be either fully or partially observed. A randomized system for the assignment of observer coverage throughout the GOA for partially observed vessels would be used to reduce potential bias in the observer data. Selecting locations for increased observer coverage would reduce the ability to randomize observer assignments and therefore potentially bias observer data. This would not meet the Council's intent to improve the quality of observer information under Amendment 76. Therefore, increase observer coverage in specific areas under Amendment 89 will not be pursued.

The Council's intent in its problem statement was to investigate the practicality of using modified nonpelagic trawl gear, similar to the requirements in the Bering Sea, as a trailing amendment to comprise a suite of management measures to protect Tanner crab. In April 2012, the Council recommended vessels using nonpelagic trawl gear to target flatfish in the Central GOA to use approved modified gear to reduce the potential adverse effects of nonpelagic trawl gear on benthic habitat and to reduce unobserved Tanner crab injury and mortality. In the GOA, fishing for flatfish includes vessels targeting shallow-water flatfish, deep-water flatfish, arrowtooth flounder, rex sole, and flathead sole. These species and species groups are defined in the annual groundfish harvest specification proposed and final rules each year.

Studies in the Bering Sea (BS) have shown that elevating the trawl sweep can reduce trawl sweep impacts effects on *C. bairdi*, *C. opilio* and red king crabs by reducing the unobserved mortality of these species. In addition, elevating the trawl sweep can reduce impacts on benthic organisms, such as basketstars and sea whips. Further research was conducted in 2011 in the GOA to identify the appropriate standards for the elevated trawl sweeps to meet the Council's desired performance standard, and to identify and resolve any implementation issues. Field testing of the modified gear demonstrated that the elevated trawl sweeps can meet the standards adopted for the Bering Sea subarea (BS) flatfish fishery (75 FR 61642, October 6, 2010) and can be used in the Central GOA flatfish fishery. For rulemaking efficiency, the revisions to the regulations for the trawl sweep modification and area closures will be combined as one action. A separate

EA/RIR/IRFA was developed to analyze the effects of the alternatives for the trawl sweep modifications, which is available at www.alaskafisheries.noaa.gov/cm/analyses.

1.3 History of this action

Since the implementation of the groundfish fishery management plans for Alaska, the North Pacific Fishery Management Council (Council) has adopted measures intended to control the prohibited species catch (PSC) of species taken incidentally in groundfish fisheries. Certain species are designated as 'prohibited' in the groundfish fishery management plans, as they are the target of other domestic fisheries. Catch of these species and species groups must be avoided while fishing for groundfish, and when incidentally caught, they must be immediately returned to sea with a minimum of injury¹. These species include Pacific halibut, Pacific herring, Pacific salmon, steelhead trout, king crab, and Tanner crab.

To further reduce the catch of these prohibited species, various control measures have been instituted in the Alaska groundfish fisheries (a history is provided in NMFS 2004, Appendix F.5). In the Gulf of Alaska (GOA) groundfish fisheries, halibut PSC (which close the groundfish target fisheries after the limits are reached) and bottom trawl seasonal and permanent closure areas to protect red king crab have been established.

The Council has at various times in the past several years requested that staff prepare and update discussion papers examining the scope of crab and salmon PSC in the GOA groundfish fisheries, and proposing management options that might be considered to regulate such removals. During this process, the Council focused the scope on two species and two areas with potentially high PSC levels: Chinook salmon (*Oncorhynchus tshawytscha*) and *C. bairdi* Tanner crab, in the central and western GOA. In October 2009, the Council chose to initiate this specific analysis, addressing protection measures for Tanner crab in the central GOA. Initial review occurred in April 2010, when the Council modified the problem statement and the alternatives, and the Council took final action in October 2010.

On July 20, 2012 (77 FR 42629) NMFS issued a final rule to implement Amendment 93 to the GOA FMP. Amendment 93 establishes separate Chinook salmon PSC limits in the Central GOA (18,316 fish) and the Western GOA (6,684 fish) annually in the directed pollock fishery. Should these limits be reached NMFS will close directed fishing for pollock in the impacted area for the remainder of the fishing year.

¹ Except when their retention is authorized by other applicable law, such as the Prohibited Species Donation Program.

2 Description of Alternatives

The alternatives evaluated in this analysis were adopted by the Council in October 2009, and modified during initial review in April 2010. In October 2010, the Council selected a preferred alternative, which is described in Section 2.1.

Alternative 1: Status Quo – No action

Under the status quo, Alternative 1, Tanner crab (*Chionoecetes bairdi*) are identified as a prohibited species in the Fishery Management Plan for Groundfish of the Gulf of Alaska (GOA Groundfish FMP), and, as such, must be returned immediately to the sea with a minimum of injury, if caught in the GOA groundfish fisheries. It is therefore incumbent upon fishermen, under the regulations, to avoid catching Tanner crab, to the extent practicable. There are no other management measures in place in the GOA that are specific to the protection of Tanner crab, although other seasonal and area closures exist which may provide ancillary benefits to Tanner crab.

Vessels fishing for groundfish in the GOA must also comply with the North Pacific Groundfish Observer Program regulations for observer coverage². The specific regulations are listed at 50 CFR 679.50, but generally, all vessels larger than 60 feet (length overall or LOA) participating in the groundfish fisheries have been required to have observers onboard at least part of the time. No vessels less than 60 feet are required to have observers onboard. Trawl and hook-and-line vessels that are 60 feet to 125 feet must have an observer onboard for 30 percent of fishing days, by quarter. Similar gear vessels that are larger than 125 feet must have an observer onboard 100 percent of the time, and shore-based processing facilities must have an observer present for 100 percent of the time. All pot vessels greater than 60 feet LOA must have observer coverage while 30 percent of their pots are pulled for the calendar year.

Alternative 2: Close the areas specified below to pot and trawl groundfish fisheries.

Component 1: Area definition

ADF&G Northeast Section

Option 1: Statistical Area 525807 and the area east of Statistical Area 525807 north of 58 degrees latitude, south of 58 degrees 15 min. latitude and west of 151 degrees 30 min. longitude.

Option 2: Chiniak Gully (Four corners at 152°19'34" W x 57°49'24" N by 57°29' N x 151°20' W by 57°20' N x 151°20' W by 57° x 152°9'20' W), excluding State waters

ADF&G Eastside Section

Option 3: Statistical Area 525702

ADF&G Southeast Section

Option 4: Statistical Area 525630

Component 2: Closure timing

² In October 2010, the Council took final action to restructure the Observer Program for vessels and processors that are determined to need less than 100 percent observer coverage in the Federal fisheries, including previously uncovered sectors such as the commercial halibut sector and the <60 feet groundfish sector. The restructured program is intended to provide NMFS with the flexibility to deploy observers in response to fishery management needs, and to reduce the bias inherent in the existing program, to the benefit of the resulting data. The restructured program was implemented at the beginning of the 2013 fishing year.

Option 1: Year round

Suboption 1: trawl gear

Suboption 2: pot gear

Suboption 3: Vessels using approved, modified gear would be exempt from closures (e.g., trawl sweep modifications or pot escape mechanisms).

Suboption 4: Vessels using pelagic trawl gear would be exempt from closures

Suboption 5: Vessels using pelagic trawl gear to directed fish for pollock would be exempt from the closures

Option 2: Seasonally (January 1 through July 31)

Suboption 1: trawl gear

Suboption 2: pot gear

Suboption 3: Vessels using approved, modified gear would be exempt from closures (e.g., trawl sweep modifications or pot escape mechanisms).

Suboption 4: Vessels using pelagic trawl gear would be exempt from closures

Suboption 5: Vessels using pelagic trawl gear to directed fish for pollock would be exempt from the closures

Alternative 3: In order to fish in the areas specified below, require 100 percent observer coverage on all trawl groundfish vessels and 30 percent observer coverage on all pot groundfish vessels less than 125 feet. Note, fishing days and observer coverage in these areas would be separate from, and not count towards, meeting a vessel's overall 30 percent groundfish observer coverage requirement.

Area definition

ADF&G Northeast Section

Option 1: Statistical Area 525807 and the area east of Statistical Area 525807 north of 58 degrees latitude, south of 58 degrees 15 min. latitude and west of 151 degrees 30 min. longitude.

Option 2: Chiniak Gully (Four corners at 152°19'34" W x 57°49'24" N by 57°29' N x 151°20' W by 57°20' N x 151°20' W by 57° x 152°9'20' W), excluding State waters

ADF&G Eastside Section

Option 3: Statistical Area 525702

ADF&G Southeast Section

Option 4: Statistical Area 525630

Note, the options and suboptions under Alternatives 2 and 3 are not intended to be mutually exclusive, and may be applied in combination. Also, in April 2010, the Council clarified that at final action, they may select closure areas that are smaller than the areas described in the four options under the 'area definition' component.

Figure 3 Area closures around Kodiak Island considered in Alternatives 2 and 3

2.1 Alternative 4, the Council's preferred alternative

In October 2010, the Council adopted the following recommendations as their preferred alternative for this action. The recommendations fall within the range of Alternatives 2 and 3, and combine elements of each. This alternative balances the protection of Tanner crab with the management of the fisheries to obtain optimum yield.

Close the area specified below to trawl groundfish fisheries, and require observer coverage for the pot groundfish fishery.

Area definition:

ADF&G Northeast Section: Statistical Area 525807 and the area east of Statistical Area 525807 north of 58 degrees N latitude, south of 58 degrees 15 min. N latitude and west of the longitude line extending north from the eastern boundary of the Type 1 red king crab closure area (Figure 4).

Closure timing: Year round

Vessels using pelagic trawl gear to directed fish for pollock would be exempt from the closures.

Observer coverage for pot groundfish fishery

In order to fish in the area, require 30 percent observer coverage on all pot groundfish vessels less than 125 feet. Note, fishing days and observer coverage in these areas would be separate from, and not count towards, meeting a vessel's overall 30 percent groundfish observer coverage requirement. The Council encourages the agency to incorporate, to the extent possible, in the new fee-based observer program, an observer deployment strategy that ensures adequate coverage to establish statistically robust observations in the area described.

Require observer coverage for the non-pelagic trawl and pot groundfish fisheries in the areas specified below

In order to fish in the areas specified below, require 100 percent observer coverage on all nonpelagic trawl groundfish vessels and 30 percent observer coverage on all pot groundfish vessels less than 125 feet. Note, fishing days and observer coverage in these areas would be separate from and not count towards meeting a vessel's overall 30 percent groundfish observer coverage requirement. The Council encourages the agency to incorporate, to the extent possible, in the new fee-based observer program, an observer deployment strategy that ensures adequate coverage to establish statistically robust observations in the areas described below.

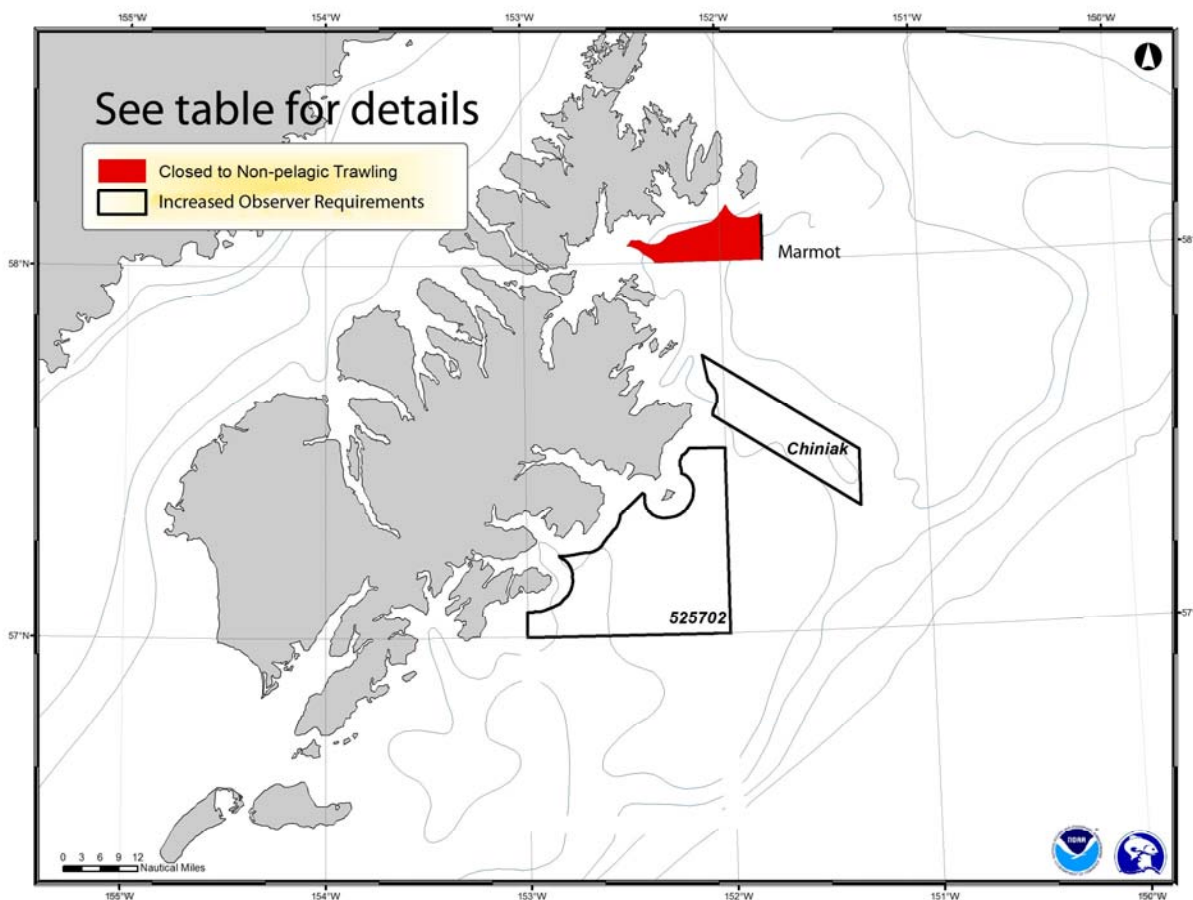

Areas:

- *ADF&G Northeast Section: Chiniak Gully* (Four corners at 152°19'34" W x 57°49'24" N by 57°29' N x 151°20' W by 57°20' N x 151°20' W by 57° x 152°9'20" W), excluding State waters (Figure 4).
- *ADF&G Eastside Section: Statistical Area 525702* (Figure 4).

Based on the Council's recommendation, NMFS, in consultation with the Council, determined that the observer options under the Tanner crab protection measures are not necessary to achieve the Council's goal to improve Tanner crab PSC data, and they will not be part of the final action. Amendment 76 to the Fishery Management Plan for Groundfish of the GOA was approved by the Secretary of Commerce on June 7, 2012 and the final rule to implement the restructured observer program was published in the Federal Register on November 21, 2012 (77 FR 70062). This amendment provides the restructure Observer Program that will improve overall catch data information for the GOA. Under the deployment plan, it is not possible to establish discrete areas with vessel specific observer requirements and maintain the random selection necessary to ensure statistically robust observations throughout the GOA. This is further explained in section 5. Because overall observer data will be improved, the restructured Observer Program will meet the Council's objective to have better information on Tanner crab PSC not only in the areas described in the option but also across the GOA.

Develop a trailing amendment to require trawl vessels to use approved modified gear, such as trawl sweep modifications, in the Central GOA nonpelagic trawl fishery. The Council's intent in its problem statement was to investigate the practicality of using modified nonpelagic trawl gear, similar to the requirements in the Bering Sea, as a trailing amendment to comprise a suite of management measures to protect Tanner crab. In April 2012, the Council recommended vessels using nonpelagic trawl gear to target flatfish in the Central GOA use approved modified gear, to reduce the potential adverse effects of nonpelagic trawl gear on benthic habitat and to reduce unobserved Tanner crab injury and mortality. In the GOA, fishing for flatfish includes vessels targeting shallow-water flatfish, deep-water flatfish, arrowtooth flounder, rex sole, and flathead sole. These species and species groups are defined in the annual groundfish harvest specification proposed and final rules each year.

Studies in the Bering Sea (BS) have shown that elevating the trawl sweep can reduce trawl sweep impacts effects on *C. bairdi*, *C. opilio* and red king crabs by reducing the unobserved mortality of these species. In addition, elevating the trawl sweep can reduce impacts on benthic organisms, such as basketstars and sea whips. Further research was conducted in 2011 in the GOA to identify the appropriate standards for the elevated trawl sweeps to meet the Council’s desired performance standard, and to identify and resolve any implementation issues. Field testing of the modified gear demonstrated that the elevated trawl sweeps can meet the standards adopted for the Bering Sea subarea (BS) flatfish fishery (75 FR 61642, October 6, 2010) and can be used in the Central GOA flatfish fishery.

	Trawl	Pot
Marmot Bay	Closed (vessels using pelagic trawl gear to fish for pollock are exempt)	Closed to pot gear unless 30 percent observer coverage
Chiniak Gully	Closed to nonpelagic trawl gear unless 100 percent observer coverage	
ADFG statistical area 525702		

Figure 4 Areas established around Kodiak under the preferred alternative, in which nonpelagic trawl gear is prohibited or nonpelagic trawl and pot vessels may only fish if they carry observer coverage

2.2 Alternatives considered but not carried forward

The discussion paper reviewed by the Council prior to the development of this analysis suggested several other management measures that could be implemented to address Tanner crab PSC. All of these other management measures presented concerns for the Council, and they were not included in the current analysis. The management measures can be found in the discussion paper reviewed by the Council in October 2009, which can be accessed at http://www.fakr.noaa.gov/npfmc/current_issues/bycatch/GOAbycatch909.pdf. Alternatives in the discussion paper included establishing PSC limits for Tanner crab, for various groundfish fisheries, which would trigger closure areas to that fishery; year-round closures by gear type; and a voluntary PSC cooperative for Tanner crab PSC management. Staff identified various strawman area closures that could be considered for either triggered or year-round closures, based on areas of high PSC or high PSC rates, by gear type. However, due to limitations in the current observer coverage in GOA groundfish fisheries, the Council identified concerns about proceeding with alternatives that rely either on establish PSC limits, or basing closure areas on observed PSC. Instead, the Council initiated the current analysis and suite of alternatives, which identify closures based on Tanner crab abundance rather than on groundfish PSC patterns.

Initially, the March 2010 analysis contained alternatives to close the proposed areas to longline, pot, and trawl gear. Jig gear was excluded because Tanner crab PSC in the jig fishery is considered to be very low. During initial review, in April 2010, the Council removed from the alternatives the option to apply the closures to longline vessels, as the analysis identified that Tanner crab PSC by longline vessels is also very low.

3 Affected Environment

This section provides background information relevant to the analysis of this action.

3.1 Description of proposed area closures

3.1.1 Area closures and groundfish management boundaries

The closed areas considered in the alternatives have been identified based on areas of high Tanner crab abundance. The closures are exclusively in Federal waters. All of the closures fall within Federal reporting area 630, which is used for managing the Federal groundfish fisheries (Figure 5).

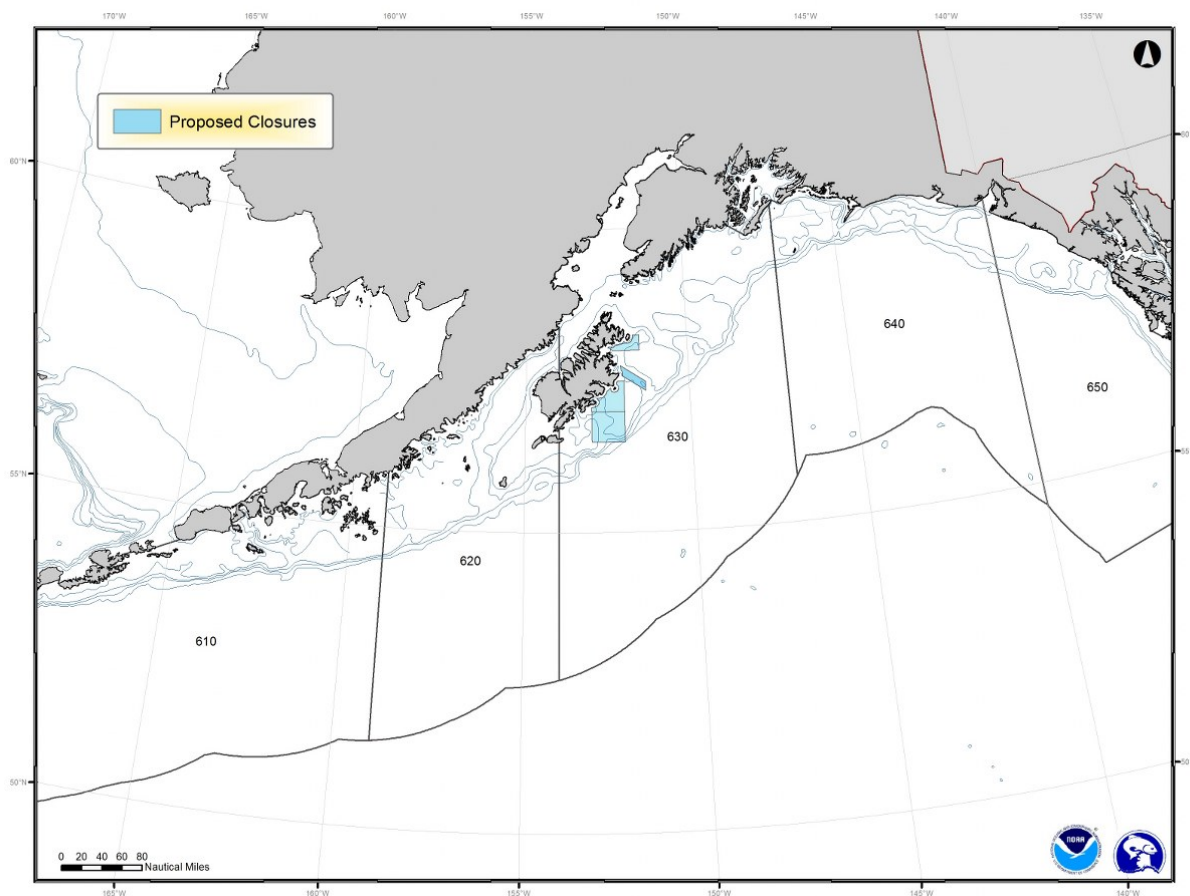

Figure 5 Maximum extent of proposed area closures, and Federal management areas

Although the proposed closure areas were based on areas of crab abundance, in some cases, the specific boundaries of the closed areas were chosen because they represent areas that are defined in existing regulations (in this case, ADF&G statistical areas), which also encompass the areas of crab abundance.

The Chiniak closure, and to a lesser extent the Marmot closure, provide some exception to this methodology, as their boundaries are not entirely those of the ADF&G statistical areas (Figure 6).

Figure 6 Maximum extent of proposed area closures, and State of Alaska statistical areas

3.1.2 Other closures in effect for groundfish fisheries in the central GOA

There are already seasonal and permanent area closures that have been implemented for the GOA groundfish fisheries, many of which were instituted to reduce PSC or interactions with Steller sea lions. It is important to consider the development of new spatial controls to reduce PSC within the context of existing time and area closures. The various State and Federal closures affecting the GOA groundfish fisheries are described below, along with their intended purpose. The year the closure was implemented is noted in parentheses. Figure 7 maps the existing closures in the Central GOA Regulatory Area, in which the area closures that are the focus of this analysis are situated.

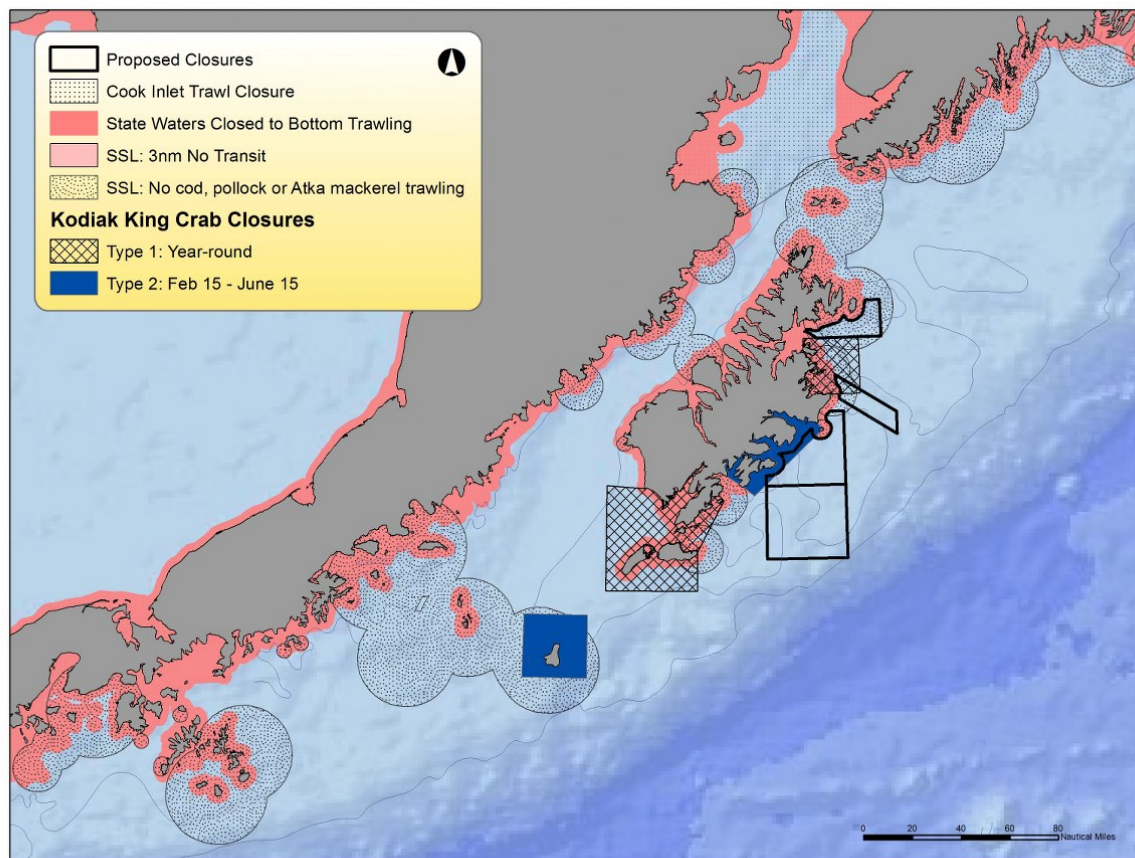

Figure 7 Locations of existing trawl fishery and crab protection closures in the Central Gulf of Alaska, and maximum extent of proposed area closures considered in this analysis

Kodiak red king crab closures: Type I and Type II (1993). **Nonpelagic trawl closure areas**, designed to protect Kodiak red king crab because of the poor condition of the king crab resource off Kodiak and because trawl PSC and mortality rates are highest during the spring months when king crab migrate inshore for reproduction. The red king crab molting period off Kodiak begins around February 15 and ends by June 15. Type I areas have very high red king crab concentrations and, to promote the protection and conservation of the crab stocks, are closed all year to all trawling except with pelagic gear. Type II areas have lower crab concentrations and are only closed to nonpelagic gear from February 15 through June 15. In a given year, there may also be Type III areas, which are closed only during specified ‘recruitment events’, and are otherwise opened year-round. Regulations governing these closures are in 50 CFR part 679 (§ 679.22(b)). These regulations state that “no person may trawl” in these areas “from a vessel having any trawl other than a pelagic trawl either attached or on board”. **There is some overlap between these closures and the proposed area closures included in this analysis.**

A research study was conducted in 1998 and 1999, at two specific sites on the boundaries of the Kodiak crab closure areas (Stone et al. 2005). The study was not able to determine the effect of the closures on their intended target, red king crab, as the species has not recovered. However, the study noted that juvenile Tanner crab were fairly common within the study areas, and were “significantly more abundant in areas closed to trawling”. The paper concludes that it is possible that habitat closures may provide benefits to Tanner crab.

Steller Sea Lion (SSL) 3 nautical mile (nm) no transit zone (2003). **Groundfish fishing closures** related to SSL conservation establish 3-nm no-transit zones surrounding rookeries to protect endangered Steller sea lions.

SSL no-trawl zones for pollock and cod (2003). **Pollock and Pacific cod trawl fishing closures** related to SSL conservation establish 10 nm to 20 nm fishing closures surrounding rookeries to protect endangered Steller sea lions. **There is some overlap between these closures and the proposed area closures included in this analysis.**

Cook Inlet bottom trawl closure (2001). **Prohibits nonpelagic trawling** in Cook Inlet to control crab PSC mortality and protect crab habitat in an areas with depressed king and Tanner crab stocks.

State Water no bottom trawling (2000). **Prohibits commercial bottom trawling** in all State waters (0 nm to 3 nm), year-round, to protect nearshore habitats and species. However, specific areas in the Shelikof Straits along the west side of Kodiak Island are open to bottom trawling from January 20 to April 30 and October 1 to November 30, and areas around Shumagin and Sanak Islands are open year round.

3.1.3 Physical characteristics of area closures

Figure 8 identifies the bathymetry within the four closure areas. Not much information is available about bottom sediment in the GOA, however what sediment information is available for the proposed area closures is mapped in Figure 9. Sediment in the proposed closure areas is variable, with similar sand and gravelly sand substrates, but also gravelly mud and silty clay areas.

Figure 8 Bathymetry within the proposed area closures (depth in fathoms)

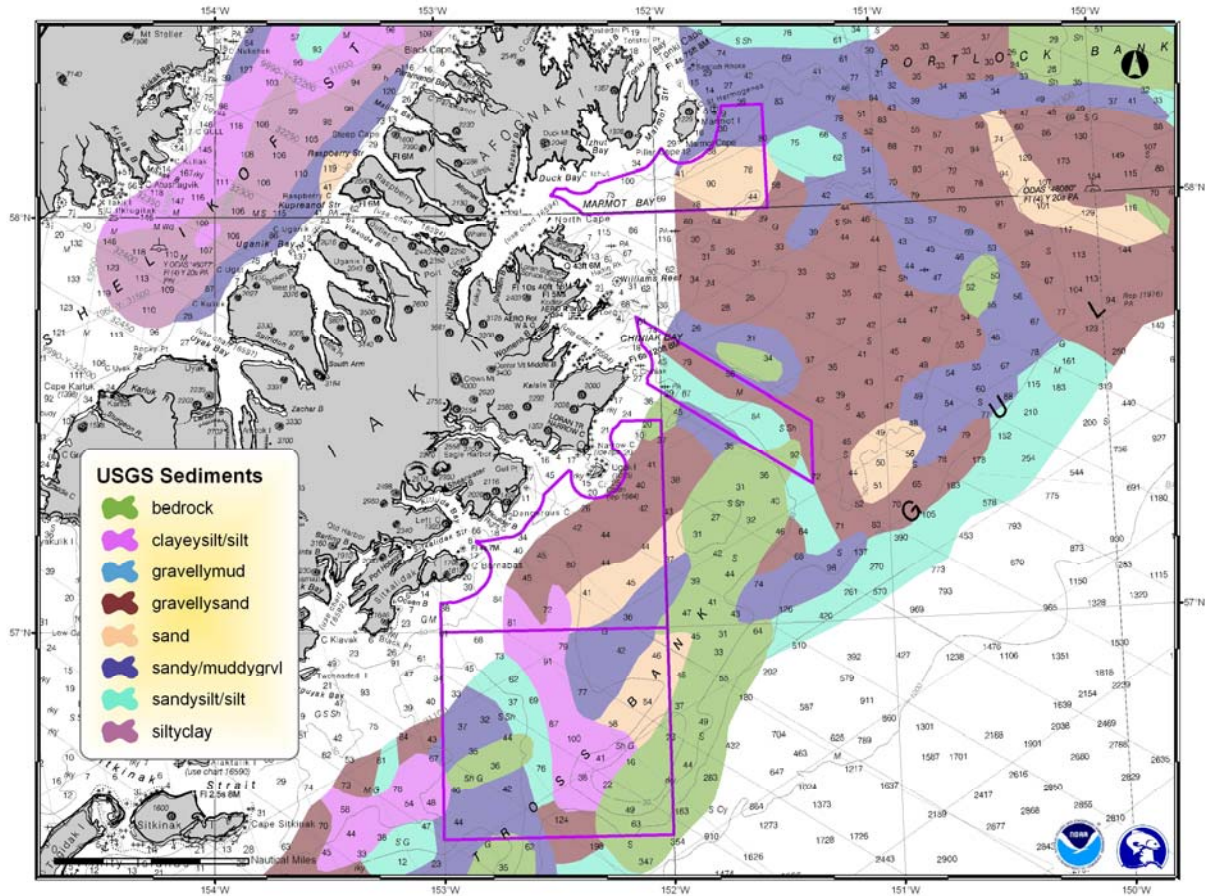

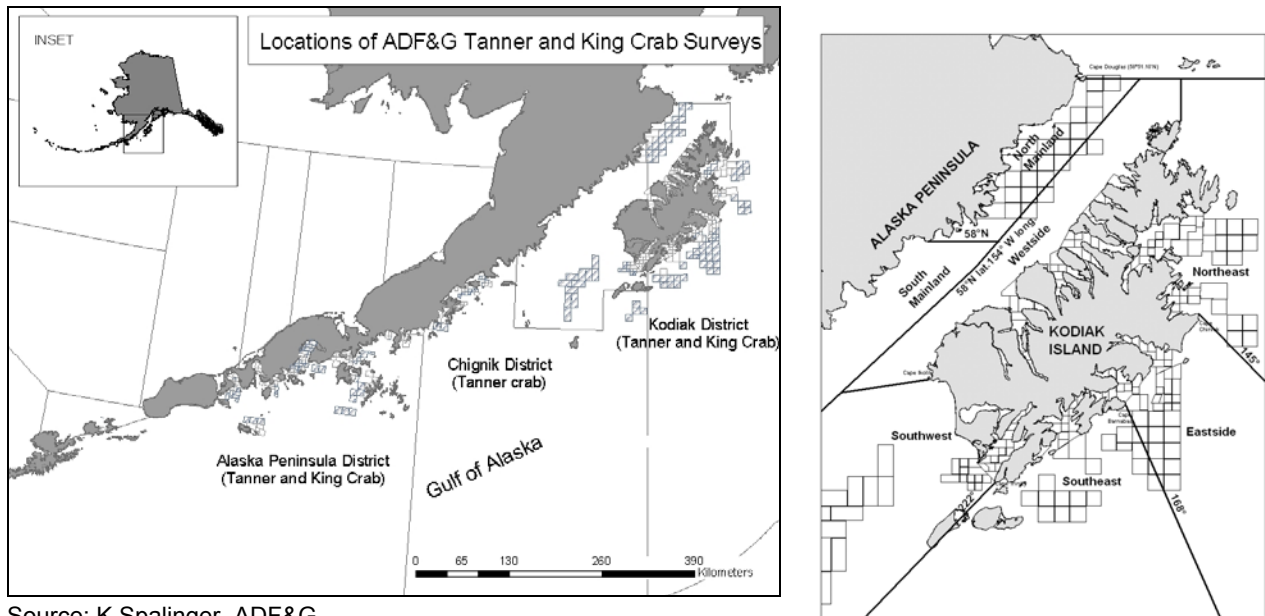

Figure 9 Sediment types within the proposed closed areas

3.1.4 Area closures and Tanner crab management boundaries

Tanner crab fisheries in the GOA are managed by the State of Alaska. Crab populations are evaluated and managed in units called districts. Fisheries south of Cape Douglas (58° 1.10' N lat.), west of Cape Fairfield (148° 50.25' W. long.), and east of Cape Kumlik (157° 27' W. long.) are part of the Kodiak District (5 AAC 35.505). The Kodiak District is further divided into seven sections to distribute harvest and effort (Figure 10).

Source: K Spalinger, ADF&G

Figure 10 ADF&G trawl survey stations for Tanner and king crab abundance, and fishery management districts around Kodiak Islands

An annual trawl survey is conducted by ADF&G, covering the Alaska Peninsula, Chignik, and Kodiak districts (Spalinger 2010). The survey methodology is designed to concentrate sampling in areas of historical king and Tanner crab abundance. While a large proportion of preferred fishing areas are surveyed, not all Tanner crab habitat is covered by the survey.

Not all of the area closures considered in this analysis are entirely surveyed by the ADF&G Tanner crab survey. Especially for closure areas 525702 and 525630, which have been identified as important for the GOA Tanner crab stock, the surveyed area is notably smaller than the statistical areas which are proposed for closure. Figure 11 shows a map overlaying the maximum extent of proposed area closures considered in this analysis over the ADF&G crab survey grid. (Note, however, that crab PSC is also observed in the areas outside of the survey area, but within the statistical areas identified as proposed closures, as described in Section 3.3.4 and illustrated in the color figures in Appendix A). While Tanner crab are found outside the station grid, the majority of the population is believed to be contained within the survey grid.

Figure 11 Closed areas considered in this analysis (shaded) and areas surveyed in the ADF&G crab trawl survey (grids)

3.2 *C. bairdi* Tanner crab stocks

Tanner crab are a member of the genus *Chionoecetes*, and are found from subtidal areas to 437 m (Jadamec et al. 1999). Tanner crab feed on a wide assortment of marine life, including worms, clams, mussels, snails, crabs, other crustaceans, and fish parts. They are fed upon by bottomfish, pelagic fish, and humans. The top 5 predators of Tanner crab in the Gulf of Alaska are Pacific cod, Pacific halibut, sculpin spp., flathead sole, and walleye pollock.

Migration patterns are not well understood; however, it is known that the sexes are separated during much of the year and move into the same areas during the reproductive season. Donaldson (1983) found that mean movement of male Tanner crab in the Kodiak area was approximately 24.0 km. In addition, male Tanner crab in bays tended to move to deeper offshore waters, while those in offshore areas tended to remain offshore (Donaldson 1983). Recent tagging research by ADF&G (ADF&G unpublished data) suggests that Tanner crab in the Eastside Section of Kodiak do not move into other sections; likewise, Tanner crab in Marmot Bay do not move south of Marmot Bay. Tanner crab that were tagged within the proposed closure areas were generally recovered within the proposed closure areas (Figure 12). It should be noted that tagging data have limitations and should be interpreted with caution. Recoveries are made

during the commercial fishery so if fishing did not occur outside the closure areas, crab would not be recovered.

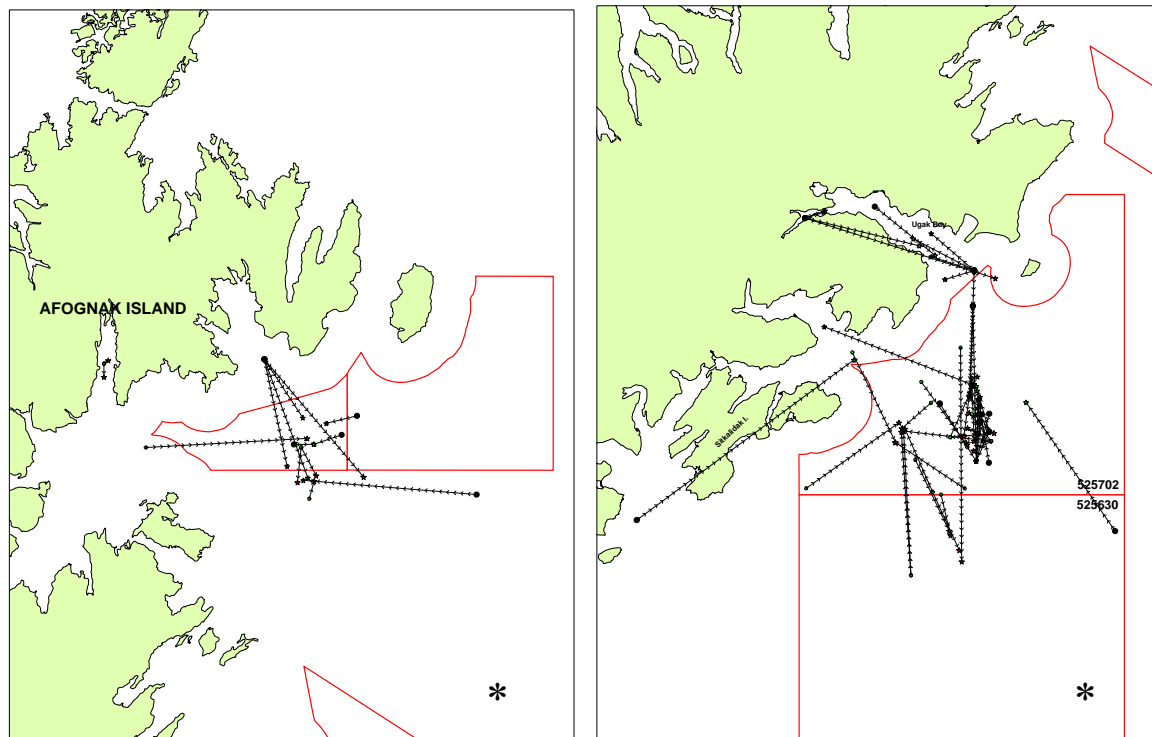

Figure 12 Tanner crab release and recovery locations from the Northeast (left panel) and Eastside Sections (right panel) 2008 and 2009. Circles denote release location, stars denote recovery location and arrows denote direct path between release and recovery.

Females mate for the first time during their last molt (maturity molt). The male crab is attracted by a chemical attractant (pheromone) released by the female. Females molt to sexual maturity and mate in the softshell condition while grasped by the male. Older hardshelled females are also mated by adult males, but in the absence of a male, they are capable of producing an egg clutch with sperm stored from a previous mating.

Fertilization is internal, and the eggs are usually extruded within 48 hours onto the female's abdominal flap where they incubate for a year. Hatching occurs late the following winter and spring with the peak hatching period usually during April to June.

The young, free-swimming larvae molt many times and grow through several distinct stages. Growth during this period is usually dependent on water temperature, but lasts about 63 to 66 days, after which the larvae lose their swimming ability and settle to the ocean bottom. After numerous molts and several years of growth, females mature at approximately 5 years of age. Males will mature at about 6 years.

Tanner crab live to an estimated maximum age of 14 years. Males of commercial size range from 7 to 11 years of age.

Data are unavailable as to the impact of climate change specifically on *C. bairdi* tanner crab stock, but climate indicators are considered during the annual stock assessment process in the ecosystem

considerations chapter of the stock assessment and fishery evaluation report for King and Tanner Crab of the Bering Sea and Aleutian Islands Management Area (NPFMC 2011b).

Commercial Tanner crab harvests in the Kodiak District date back to the late 1960s (Brown 1971; Figure 13). As Tanner crab fisheries grew in economic importance, Tanner crab populations were indexed, using a pot survey, starting in 1973 (Colgate and Hicks 1983). The annual trawl survey did not begin until the early 1980s (Colgate and Hicks 1983), after the Tanner crab population had declined. Since implementation of the trawl survey, the highest harvest of Tanner crab was just over 5 million pounds (1989), and has averaged less than 2 million pounds.

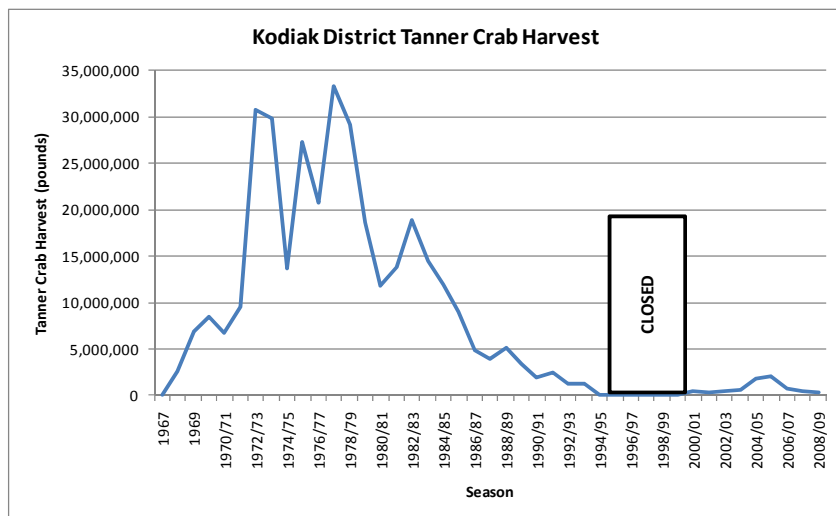

Figure 13 Kodiak District Commercial Tanner crab harvest, 1967 through 2008/2009

Because of the differences in survey methods, it is difficult to make direct comparisons pre- and post-1988 survey data. Harvests prior to the start of the trawl survey often exceed 10 million pounds suggesting that populations in the 1970s were much larger (Stichert *in press*). In addition to higher harvests, historical effort was much broader throughout the management area than current fishing effort (Figure 14).

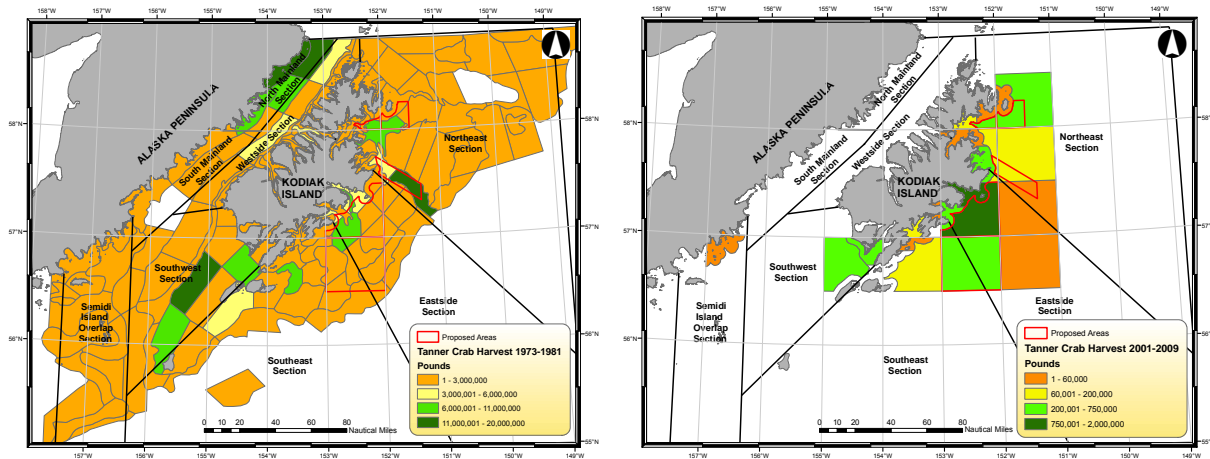

Figure 14 Historical harvest locations, summing harvests 1973 through 1981, compared to current harvest locations, summing harvests 2001 through 2009

Historically, harvests were strongest in Chiniak Gully, south of Kodiak Island, and along the North Mainland. Current harvest locations are predominately on the Eastside of Kodiak Island.

From 1997 through 2009 the total Tanner crab population in the Kodiak District ranged from just over 19 million crabs to over 186 million crabs (Spalinger 2010; Table 1). The average Tanner crab population estimate from 2003 through 2009 is approximately 109 million crabs. The management section that consistently has had the highest population of Tanner crab is the Eastside Section, which has averaged over 48 million crabs from 2003 through 2009. The section with the second highest abundance is the Northeast Section which has averaged over 17 million crabs from 2003 through 2009.

Table 1 Population estimates for total numbers of Tanner crab for Kodiak District, by section from the ADF&G bottom trawl survey

Year	Northeast	Eastside	Southeast	Southwest	Westside	North Mainland	Kodiak District
1997	3,550,650	4,578,002	1,379,455	1,172,719	2,113,986	6,754,956	19,549,768

Source: Spalinger *in press*

Similar to the trends of the total Tanner crab population, mature Tanner crab population estimates are highest in statistical area 525702 and inside State waters of Marmot Bay (statistical area 525805; Figure 15).

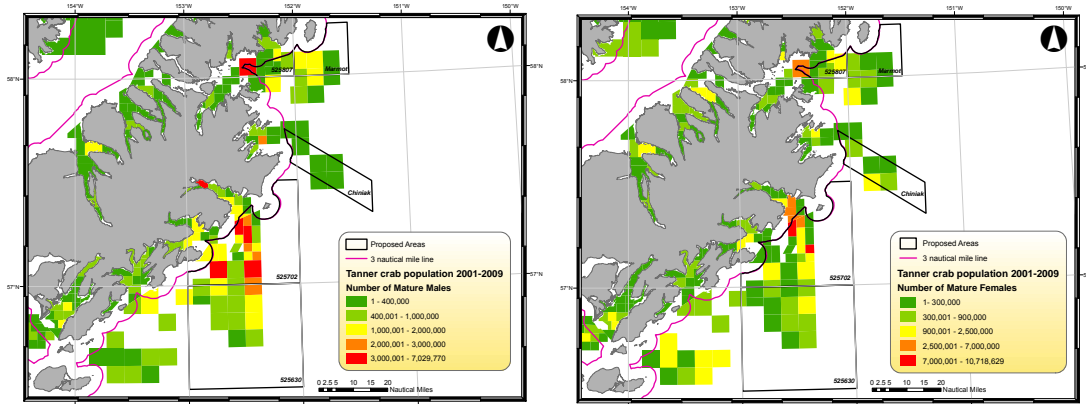

Figure 15 Numbers of mature male and mature female Tanner crab as surveyed by the ADF&G trawl survey, summed 2001 through 2009

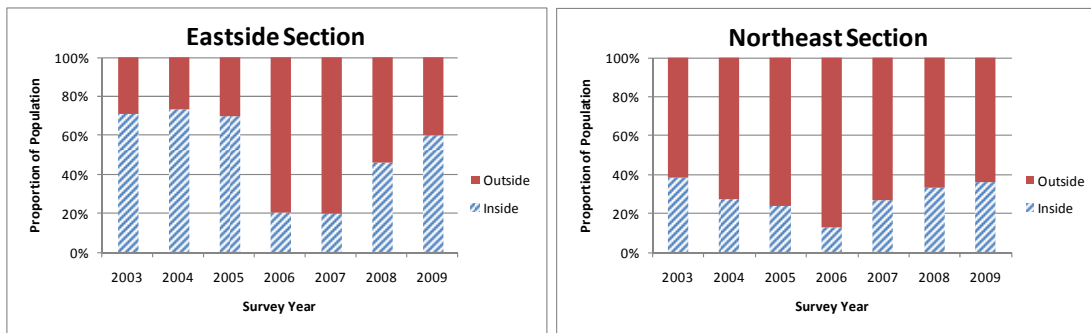

3.2.1 Tanner crab abundance inside area closures considered in this analysis

The proposed area closures that are considered in this analysis are located in the Northeast and Eastside sections of the Kodiak District. The proposed closure in statistical area 525807, the “boot”, and the proposed Chiniak closures are in the Northeast Section. The proposed 525702 and 525630 closures are in the Eastside Section. Estimates of Tanner crab populations within the proposed area closures range from just over 16 million crabs (2006) to over 38 million crabs (2003 and 2008) and average 22.7 percent of the total Kodiak District population (Table 2). The proportion of crab inside the area closures in the Eastside Section ranged from 20 percent to 71 percent of the total Eastside Tanner crab population estimate. The proportion of crab inside the proposed closures in the Northeast Section was generally lower, ranging from 13 percent to 39 percent of the total Northeast Tanner crab population estimate (Table 2 and Figure 16).

Table 2 Population estimates for Tanner crab inside and outside proposed area closures (boxes) in the Eastside (525702 and 525630) and Northeast (Marmot and Chiniak) sections in relation to the total Kodiak District population estimate, 2003 through 2009

Year	Kodiak District		Inside Proposed Boxes			% of Kodiak Total inside Box
	Total		Eastside	Northeast	Total	
2003	70,417,505		25,686,289	5,187,889	30,874,178	43.8%
2004	70,743,886		19,355,934	4,509,878	23,865,812	33.7%
2005	67,676,188		13,306,984	4,122,476	17,429,460	25.8%

Figure 16 Estimated Tanner crab population outside the proposed area closures (boxes) in the Eastside (525702 and 525630) and Northeast (Marmot and Chiniak) Sections relative to state and federal waters, 2003 through 2009

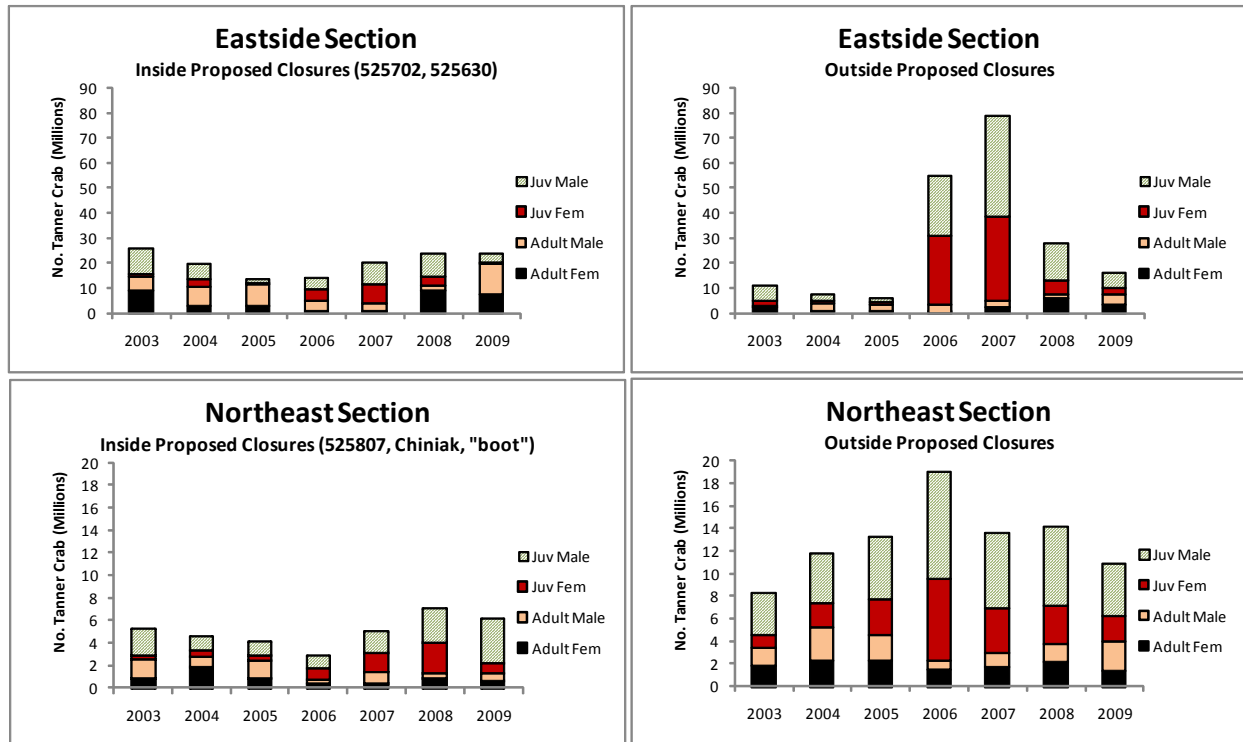

Bottom trawl gear is prohibited inside most state waters of the Kodiak Area and from all state waters in the Tanner crab management sections with the proposed closures. Tanner crab populations are distributed inside and outside the 3-mile state-water boundary. In the Eastside Section of the Kodiak District, the entire surveyed Tanner crab habitat outside of state waters is contained within the proposed area closures. In the Northeast Section of the Kodiak District, portions of the Tanner crab population are outside state waters and outside of the proposed area closures (Figure 17).

Source: N. Sagalkin, ADF&G

Figure 17 Estimated Tanner crab population outside the proposed area closures (boxes) in the Northeast Section relative to state and federal waters, 2003 through 2009

In general, the majority of the Tanner crab population in the Northeast Section outside of the proposed area closures is located within state waters (Figure 17). Tanner crab population estimates are comprised of juvenile and mature, male and female crab. Figure 18 demonstrates the composition of Tanner crab inside the proposed area closures in the Eastside Section of the Kodiak District. Comparing the population composition (Figure 18) in relation to the proportion of the population inside and outside the proposed area closures (Figure 16), illustrates some spatial patterns that exist in the Eastside Section where mature crab tend to be offshore. This pattern is less evident in the Northeast Section (Figure 18).

3.2.2 *C. bairdi* Tanner crab life history and seasonal patterns

Tanner crab are found mainly on soft bottom and most abundant in depths of 40 fathoms to 50 fathoms (Urban and Hart 1999). Tanner crab may be more sensitive to disturbance during molting, mating, and egg hatching periods than during other portions of the year. While males appear to have synchronous molting in the spring (ADF&G unpublished data; Table 3), there are fewer data on the timing of female molting, except for the female molt to maturity.

The first time female Tanner crab mate is during their molt to maturity. Final molt for females may occur as early as December and as late as June (Donaldson and Adams 1989; Donaldson 1975; Table 3). Females molt to sexual maturity and mate in the softshell condition while grasped by mature male (primiparous females). Peak of egg deposition for primiparous female Tanner crab occurs in April and May (ADF&G unpublished data; Table 3). After the maturity molt, females do not continue to grow, but do continue to mate and produce eggs (multiparous females). Primiparous females tend to mate with males in shallow waters in isolated pairs, while multiparous females mate in large aggregations in deeper waters during April, May, and June (Stevens et al. 1994; Table 3); this differential mating behavior is termed bipartite breeding (Somerton 1982). Mating behavior is intricate and may last several days (Adams 1982; ADF&G unpublished data). Some authors have suggested that groundfish trawls could easily capture or disrupt an entire Tanner crab mating aggregation (Stevens 1990).

3.3 C. bairdi Tanner crab PSC in Federal groundfish fisheries

In this section, an overview of Tanner crab PSC in the Federal groundfish fisheries is provided, both by reporting area and specifically in the proposed area closures that are considered in this analysis. Although some information is given on crab PSC as a proportion of overall groundfish effort, more detail on groundfish effort is provided in the RIR, in Section 6.5.

In order to understand the PSC information presented, the first two subsections below provide some context to the PSC overview. Section 3.3.1 describes the proportion of groundfish fishing effort, by gear type and target fishery, which is observed in the central GOA. The reported numbers of total PSC are extrapolated based on the rates of PSC on observed vessels, using a procedure described in Cahalan et al. (2010). Section 3.3.2 provides information about the various studies of crab PSC mortality rates that have been conducted for various gear types. The numbers reported here of PSC the groundfish fisheries do not account for the differing levels of mortality that may affect crab caught by different groundfish gear types. Finally, in Section 3.1.2, the existing area closures that affect some or all gear types in the groundfish fisheries around Kodiak are described, which provides context for understanding the constraints that are already in place for certain gear types.

3.3.1 Observer coverage

Catch and PSC data were obtained from the NMFS catch accounting database, and analyzed to represent the amount, species composition, timing, and location of salmon and crab PSC in GOA groundfish fisheries. All NMFS data were screened to ensure confidentiality is maintained. The process that is used to estimate PSC for groundfish fisheries is described in Cahalan et al (2010). In short, PSC estimates are derived from observer information. If a trip is unobserved, then PSC rates from observed vessels are applied to the industry report of retained groundfish catch. The resulting estimates are used in this analysis. Further discussion on the proportion of GOA groundfish fisheries that are observed is addressed below.

Spatial analysis of PSC in this analysis uses only the data directly from observed vessels, as described below; represent only a proportion of total catch in the groundfish fisheries.

The North Pacific Groundfish Observer Program collects catch and PSC data used for management and inseason monitoring of groundfish fisheries. Since 1990, all vessels larger than 60 feet (length overall) participating in the groundfish fisheries have been required to have observers onboard at least part of the time. It is important to note that in a separate initiative, the Council has tasked staff with analyzing alternatives to address known problems with the existing system of observer procurement and deployment. While several issues are being addressed in that analysis, potential bias of catch and PSC estimates are a key element, particularly in fleets with less than 100 percent observer coverage. Concerns about data quality are intended to be addressed through the Observer Program restructuring initiative. More information about the observer restructuring initiative is in Chapter 5 of this document.

Under the structure of the current Observer Program, the amount of observer coverage is based on vessel length. No vessels less than 60 feet are required to have observers onboard. Trawl and hook-and-line vessels that are between 60 feet and 125 feet must have an observer onboard for 30 percent of fishing days, by quarter. Vessels that are larger than 125 feet that are not fishing with pot gear must have an observer onboard 100 percent of the time. All vessels that are greater than 60 feet LOA fishing with pot gear must have observer coverage for 30 percent of their pot retrievals each quarter. Shore-based processing facilities that process 1,000 mt or more of groundfish in a month must have an observer present for 100 percent of the time. Facilities that process between 500 mt and 1,000 mt per month are required to have observer coverage on 30 percent of their processing days.

There is a greater prevalence of smaller vessels participating in the GOA groundfish fisheries than in the Bering Sea/Aleutian Islands, and over the past 10 years, participation by smaller vessels in the GOA groundfish fisheries has generally increased, particularly catcher vessels less than 60 feet length overall (NPFMC 2003). Because observer coverage requirements are generally based on vessel length, the proportion of total catch that is observed in GOA groundfish fisheries is much lower than, for example, in the Bering Sea fisheries. The majority of the GOA fleet is subject to 30 percent observer coverage. Table 4 illustrates the total groundfish catch in the GOA, the total amount of groundfish that is caught while an observer is onboard the vessel, and the resulting percentage. In the Central GOA the range is from 32 percent to 37 percent. In comparison, the average percentage of observed catch in the Bering Sea is approximately 86 percent, and in the Aleutian Islands is approximately 95 percent. Please note that the percentage of observed catch provides only a gross overview as to the quality of information, and may mask data quality concerns. The goal is to have an unbiased estimate that is sufficiently precise to meet the management need for the information. The precision of PSC estimates depends upon the number of vessels observed and the fraction of hauls sampled (Karp and McElderry 1999). Because of the relatively lower levels of observer coverage in the GOA, estimates of salmon and crab PSC are less precise than in Bering Sea groundfish fisheries. To what degree they are less precise, however, is not known, as current PSC estimates do not include a measure of uncertainty.

Detailed information on percent of harvest observed in the GOA groundfish fisheries has been presented to the Council as part of its report from the Observer Advisory Committee, at the April 2008 Council meeting. NMFS compiled a series of tables that provide a breakout of the percentage of harvest observed for each year 2004 through 2007, inclusive, in order to show the effective rate of coverage in particular target fisheries. The data are broken out by observer coverage category (30 percent, 100 percent), gear type, area, and component of the catch by the <60 feet LOA fleet that is unobserved.³ The information for the central GOA is presented in Table 5.

Information in the tables pertinent to the discussion of fisheries in the GOA is summarized below. For the GOA Pacific cod pot fisheries, more than half the catch from 2004 through 2007 came from the <60 feet fleet, which is unobserved. The remaining catch primarily came from the >60 feet to <125 feet fleet where percent coverage ranged from 17 percent to 28 percent over the four years. For the Pacific cod trawl fisheries delivering shoreside, coverage in the >60 feet to <125 feet category ranged from 24 percent to 30 percent in this time frame. The State waters Pacific cod fishery is unobserved; however PSC rates from comparable vessels/areas are applied to the State waters Pacific cod catch. PSC attributable to the State waters Pacific cod fishery is included in this analysis, but is presented in a separate section.

³ Note that the total catch data referenced is from the NMFS catch accounting system, and the observer data is from the NMFS observer database. The observer data include all sampled and unsampled hauls that occurred while an observer was onboard. High variability in percent observed catch among years has been correlated to several factors, such as the varying season lengths, number of participating vessels, different catch rates per year, weather, and market prices.

Table 4 Total catch, observed catch, and percent observed catch by area and year

Area	Year	Total (mt)	Observed (mt)	Percent
Western GOA	2004	50,853	14,414	28%
	2005	53,142	13,195	25%
	2006	51,944	17,253	33%
	2007	46,968	16,882	36%
Central GOA	2004	108,707	37,744	35%
	2005	120,030	41,586	35%
	2006	131,271	42,349	32%
	2007	118,871	44,113	37%
Eastern GOA	2004	7,610	2,911	38%
	2005	8,709	3,072	35%
	2006	8,772	3,293	38%
	2007	4,274	3,225	75%
Bering Sea	2004	1,695,228	1,450,413	86%
	2005	1,702,671	1,467,153	86%
	2006	1,696,337	1,470,680	87%
	2007	1,569,110	1,352,914	86%
Aleutian Islands	2004	98,169	93,188	95%
	2005	94,209	89,516	95%
	2006	95,288	91,461	96%
	2007	107,090	101,060	94%

Note: This table does not include jig gear, but otherwise includes all targets.

Source: http://www.fakr.noaa.gov/sustainablefisheries/inseason/percent_observed.pdf

For the pollock pelagic trawl fishery, the data are mostly confidential for the unobserved <60 feet fleet each year. The remaining catch came from the >60 feet to <125 feet fleet where coverage ranged from 31 percent to 37 percent over the four years. For nonpelagic trawl arrowtooth flounder and shallow water flatfish targets delivered shoreside, the majority of the catch was in the >60 feet to <125 feet category and percentage covered ranged from 13 percent to 34 percent over the three-year period. Catch of flatfish in the catcher processor fleet was largely in the >60 feet to <125 feet category, with the exception of arrowtooth flounder in the Central GOA, and percentage covered varied widely.

Source: http://www.fakr.noaa.gov/sustainablefisheries/inseason/percent_observed.pdf

Notes for Table 5:

These tables do not include data from shoreside processors using paper weekly production reports because the data are at the processor level. The vessel length associated with the catcher vessels delivering to the shoreside processor is not available. This includes 5,717 mt of total groundfish catch in the GOA, consisting of 19 processors in 2004, 11 processors in 2005, and 8 processors in 2006 in the GOA.

1. Values where total and observed columns are blank (-) indicate confidential data. Confidential data have been defined as <3 vessels and processors for that given year, area, sector, gear type, target fishery, and vessel length.
2. Total catch data are from the catch accounting system, and the observer data are from the observer database in March 2008.
3. Harvest sector: S=shoreside; CP/M=catcher processor or mothership
4. Gear type: HAL=hook-and-line; JIG=jig (not included in this table); NPT=nonpelagic trawl, POT=pot; PTR=pelagic trawl
5. Vessel length: <60=vessels less than 60 feet length overall (LOA); ≥60' and <125'= vessels greater than or equal to 60 feet and less than 125 feet LOA; ≥125'=vessels greater than or equal to 125 feet LOA
6. Year= target fishery year
7. Weight is rounded to the nearest mt.
8. Percent= (mt of observed catch/mt of total groundfish catch in catch accounting system)*100
9. Not included in the GOA are trip target fisheries per gear type: HAL= pollock, deepwater flatfish, rockfish, other species, arrowtooth (2,406 mt shoreside, 404 mt CP/M); NPT= pollock, deepwater flatfish, shallow water flatfish, rockfish, flathead sole, other species, sablefish (21,367 mt shoreside, 1,633 mt CP/M); POT= pollock, other species (18 mt shoreside); PTR= Pacific cod, shallow water flatfish, flathead sole, other species, arrowtooth, sablefish (2,220 mt shoreside, 566 mt CP/M)
10. For CPs and motherships groundfish catch estimates, the catch accounting system uses weekly production reports for vessels ≥60 and <125 and observer data for vessels ≥125 except for pot gear uses weekly production reports for vessels ≥60.
11. In some cases, the observed data are higher than the total catch for a given area, sector, gear type, target fishery, vessel length. There are several reasons that this occurs:
 - a. In 2004 through 2006, four CPs ≥125 feet, had haul data considered to be invalid by the Observer Program. These data were replaced with weekly production reports in the catch accounting system, but are still used as the observed total.
 - b. For catcher/processors and motherships ≥60' and <125', there can be a mismatch between the trip target that is assigned from the observed data and the trip target that is assigned based on weekly production report data. This occurs when a vessel targets more than one species during a week.
 - c. For the shoreside sector, the total catch is based on fish tickets, which could be different from the observer data.
 - d. The two databases include separate sources of information. The catch accounting system partially uses weekly production reports, landing reports, and observer data. Production reports are focused on different goals from the observer data (production vs. total catch accounting), uses a different method to determine catch and targets, and in the cases of 30 percent observer coverage, include dissimilar time frames of estimates, especially at the target level (i.e. observer data may not cover the entire week upon which a production report is based).
12. A high level of variability in the percent observed catch for a given target fishery may be explained by the level of coverage that vessels had prior to entering a different FMP area. Observer coverage is by quarter and by fishery category, not by FMP area. A 30 percent vessel may have enough observer coverage in one FMP area to meet the requirements for their fishing in another FMP area. A high level of variability in percent observed catch also may be attributed to a variable number of vessels that participate in certain GOA fisheries each year.
13. This is NMFS' approach to the OAC data request, as of March 26, 2008.

3.3.2 Mortality Rates

PSC mortality in trawl gear

The Council has consistently used an estimated mortality rate of 80 percent for crab PSC in trawl fisheries in its analyses, since the early 1990s (Table 6). This rate is an approximation based on a trawl research study conducted in 1987 in the BSAI joint venture fisheries (Stevens 1990). Species targeted were yellowfin sole, rock sole, and Pacific cod. The study found that 21 percent of the king crabs and 22 percent of the Tanner crabs captured in Bering Sea trawl fisheries survived at least two days following capture. A few earlier studies also looked at PSC mortality in the trawl fisheries (Blackburn and Schmidt 1988, Owen 1988, Fukuhara and Worlund 1973, Hayes 1973), which generally indicated that soft shell crab are much more vulnerable to impacts from trawling than hard shell crab, and that mortality appears to be directly correlated with time out of water. This latter finding was also apparent from the Stevens study, which noted that captivity time (which includes both towing time and deck sorting time) may have been longer in the study than it would be in a normal fishery, especially for king crab. The Blackburn and Schmidt (1988) and Owen studies (1988) were both conducted around Kodiak.

Table 6 History of mortality rate calculations for crab PSC in groundfish fisheries, in research studies and Council analyses

Study		King crab			Tanner/snow crab			Notes/rationale
		Trawl	Pot	Longline	Trawl	Pot	Longline	
Study on observed crab PSC viability in domestic trawl fishery around Kodiak, 1978-1981	Blackburn and Schmidt 1988	1-21%			12-17%			Red king and Tanner crab study. King crab: found 1% mortality for hard shell, 2% injured for hard shell, and 21% mortality for soft shell. Tanner: found 17% mortality overall, but excluding one unusual tow averages to 12 % mortality overall; 36% of crab injured.
Research study on crab PSC on west side of Kodiak, trawling for flatfish	Owen 1988	19%			12%			Red king and Tanner crab study (but low king crab sample size). No soft shell crab caught.
1987 trawl comparison research study on PSC in BSAI joint venture fishery targeting yellowfin sole, rock sole, Pacific cod	Stevens 1990	78%			79%			Red king crab and Tanner crab study. Mortality rate directly proportional to captivity time (which in study may have been longer than is normal in fishery), especially for king crab (at 3 hours captivity, 0% mortality, at 17 hours, 100% mortality).
1990 Observer Program study of condition factor of crab PSC	Guttormsen et al 1992	20.1% (+27.5 % poor)	0% (+0% poor)		37.5% (+32.0 % poor)	1.3% (+1.4 % poor)	7.5% (+21.7% poor)	Observers identified 3 condition factors: excellent, poor, dead. No estimate available for longline king crab PSC.
BSAI groundfish FMP amendment 24 (Pacific cod gear allocations)	NMFS 1993	80%	37%	37%	80%	30%	45%	Trawl mortality rate based on Stevens 1990; pot and longline rates proportionally adjusted from Guttormsen et al 1992, so that trawl = 80% as per Stevens 1990.
BSAI groundfish FMP amendment 37 (Bristol Bay nearshore closure)	NPFMC 1996	80%	8%	37%	80%	30%	45%	Mortality rates supposedly based on NMFS 1993, no explanation for change in pot king crab rate.
BSAI crab FMP amendment 11 (Tanner crab rebuilding)	NPFMC 2000				80%	35%	35%	Mortality rate for combined fixed gear, based on NPFMC 1996; assumes average 2/3 of PSC from pot gear (30% mortality rate) and 1/3 from longline gear (45% mortality rate)
BSAI crab FMP amendment 14 (Snow crab rebuilding)	NPFMC 2000				80%	20%	20%	Mortality for combined fixed gear, no rationale in analysis for change in mortality rate
BSAI crab FMP amendment 15 (St Matthew blue king crab rebuilding)	NPFMC 2000	80%	8%	37%				Mortality rates based on NPFMC 1996

Study		King crab			Tanner/snow crab			Notes/rationale
		Trawl	Pot	Longline	Trawl	Pot	Longline	
Chapter on BSAI PSC in Council's BSAI Crab SAFE reports	NPFMC 2001-2007	80%	20%	20%	80%	20%	20%	No rationale in analysis for choice of mortality rates. May have averaged fixed gear rates for king crab from NPFMC 1996, and used fixed gear rate from NPFMC 2000 (snow crab rebuilding) for Tanner/snow crab.
BSAI PSC considered as part of stock assessments in BSAI Crab SAFE reports	NPFMC 2008-2009	80%	80%	80%	80%	80%	80%	Crab Plan Team directive in 2008 SAFE report to use 80% for PSC in groundfish fisheries (presumably because most PSC was assumed to be from trawl)
BSAI PSC considered as part of stock assessments in BSAI Crab SAFE report	NPFMC 2010	80%	50-80%	50-80%	80%	50-80%	50-80%	Pribilof Is red, blue, and golden king crab, AI golden king crab, and Adak red king crab assessments use 50% mortality for fixed gear; others use 80%
2010 AFSC study on crab PSC mortality on GOA trawl vessels targeting arrowtooth (ATF) and shallow water flatfish (SWF)	preliminary results				32-68% overall average 46%			Assessments made on six GOA vessels, half of each target. Reflex action mortality predictor tests used to estimate PSC mortality rates of Tanner crab. Average for arrowtooth flounder target: 37%; average for shallow water flatfish target: 52%.

This analysis “assumes” an 80 percent mortality rate for Tanner crab PSC taken by trawl gear, based on observed mortality rates (as indicated in Table 6) and the Council’s approximations based on a trawl research study conducted in 1987 in the BSAI joint venture fisheries (Stevens 1990). However, in 2010, scientists of the Alaska Fisheries Science Center’s (AFSC) Resource Assessment and Conservation Engineering Division worked with the Alaska Groundfish Data Bank (AGDB) to improve the information available to assess the effects of bottom trawling on Tanner crab of the Gulf of Alaska. This has included collecting information on the condition of crabs released after capture by vessels targeting arrowtooth flounder and shallow-water flatfish (the two fisheries with highest Tanner crab PSC), as well as collecting information on the characteristics of trawls used by GOA vessels to assess the applicability of research estimating unaccounted for crab mortality from Bering Sea fisheries.

Scientists accompanied six GOA vessels on trawl trips, three targeting arrowtooth flounder (ATF) and three targeting shallow-water flatfishes (SWF). They made reflex assessments on Tanner crabs (*C. bairdi*) taken as PSC, just before their return to the water. Assessments consisted of testing for the presence or absence of six specific reflexes and using the number of missing reflexes as a reflex action mortality predictor (RAMP). Stoner et al. (2008) established a relationship between RAMP scores and delayed mortality for Tanner crabs following trawl encounters in the Bering Sea. That relationship was used to estimate PSC mortality rates for the Tanner crab captured by these vessels. Crabs taken as PSC are subjected to longer periods out-of-water than those from the unobserved mortality studies (e.g., Stoner et al. 2009).

A total of 1,265 crabs were assessed, 820 during ATF trips and 445 from SWF trips. Average estimated mortality varied significantly between vessels, from 32 percent to 54 percent for the ATF vessels and from 38 percent to 68 percent for SWF trawling. Overall, mortality averages were 37 percent for the ATF

trips, 52 percent for SWF trip, and 46 percent overall. These are all substantially below the assumed 80 percent PSC mortality estimate currently used for trawl PSC mortalities for Tanner crabs. That estimate was based on Stevens (1990), who studied catches of joint-venture trawls delivered to a Soviet mothership in the Bering Sea, with relatively long processing times. The 2010 data reported here are more likely reflective of current GOA bottom trawl fisheries, but the 80 percent is used to be more conservative to the benefit of the Tanner crab for purposes of this analysis.

Preliminary observations during sampling, and patterns in the estimated mortalities indicated several operational differences likely affecting mortality outcomes. Probability of mortality increased the longer a crab was out of the water. When, after encountering large crab numbers, a vessel moved to an area with few crab, the few crab in subsequent tows had very poor reflex assessments. This would be explained if those particular crabs had remained in the net from the previous tows and were thus subjected to additional time out of water and at least one additional tow. Handling differences that could affect mortality rates were also apparent. Increasing awareness of these factors could be used to improve crab mortality rates for these fisheries.

PSC mortality in fixed gear

Since the 1990s, various mortality rates have been used for crab PSC in the fixed gear groundfish fisheries in the analysis of Council amendments (Table 6). No direct research studies have been conducted on mortality of crab caught as PSC in the longline or pot groundfish fisheries. A study was conducted through the observer program in 1990 that evaluated the condition of crab caught as PSC in the groundfish fisheries. Combining these results with the Stevens (1990) research that looked at trawl mortality, a calculation was made for a 1993 Council analysis to scale the mortality results from the observer study for pot and longline crab PSC upwards, proportional to the difference between the observer study and Stevens' findings for trawl crab PSC. Consequently, the Council's 1993 analysis used 30 percent pot and 45 percent longline mortality rates for Tanner crab PSC, and 37 percent mortality rates for both gears for king crab PSC⁴. These rates were also used in subsequent Council analyses for several years, with the exception that the NPFMC (1996) changed the pot PSC mortality rate for red king crab to 8 percent (the rationale for this change is not clear, but is likely from research in the directed crab fishery about mortality rates of crab PSC in crab pots). In 2000, the Council's snow crab rebuilding amendment assigned a 20 percent mortality rate to PSC from the pot and longline groundfish fisheries, but it is not clear what the rationale was for this change. This rate did, however, get perpetuated for much of the 2000s in the Council's PSC chapter in the BSAI Crab SAFE report, and the 20 percent rate was also applied to king crab PSC (again, the rationale is not entirely clear, but may result from an averaging of the 8 percent pot mortality rate and 37 percent longline mortality rate that had previously been used).

With the implementation, in 2008, of overfishing limits in the BSAI Crab SAFE, and assessments that accounted for total catch, the Crab Plan Team issued a recommendation that all assessments should use an 80 percent mortality rate for all PSC in the groundfish fisheries, under the assumption that most of the PSC originated from trawl vessels. Following a presentation to the Crab Plan Team in 2009 about the occurrence of crab PSC in the pot and longline groundfish fisheries, the assessment authors have now begun to distinguish among gear types in accounting for crab PSC in the groundfish fisheries. A 50 percent mortality rate is currently applied to crab PSC in the directed Tanner crab pot fisheries. Consequently this rate is now also being applied to all crab PSC in the fixed gear groundfish fisheries (where the assessment distinguishes PSC among gear types).

Previous discussion papers on PSC in the GOA groundfish fisheries, and the initial review draft of this analysis, did not calculate the mortality associated with crab PSC, due to the variability associated with mortality rates. The Council discussed this issue at the April 2012 Council meeting, and requested that the

⁴ There were no results for longline red king crab PSC in the observer study; consequently, it is assumed that the pot mortality rate was simply cross-applied to longline gear.

data be presented with mortality rates. Consequently, to account for the variability in fixed gear rates, **this analysis evaluates both 20 percent and 50 Tanner crab percent mortality rates for fixed gear PSC.**

3.3.3 Overview of PSC by area, gear type, and target fishery

In the GOA, *C. bairdi* PSC primarily occurs in the western and central regulatory areas, and corresponds to the locations of the trawl and pot fisheries. Table 7 illustrates PSC for 2003 through 2009, for reporting areas in the western and central GOA. Crab PSC Catch in the eastern regulatory area is negligible. Given that the proposed area closures considered in this analysis are all located in reporting area 630, from this point forward, the PSC overview will focus on this particular reporting area.

Table 7 *C. bairdi* PSC (number of crab) in the western and central GOA, 2003 through 2009, in Federal⁵ groundfish fisheries

Year	610	620	630
2003	7,388	24,033	116,814
2004	12,313	4,576	50,217
2005	45,865	7,037	111,129
2006	9,912	67,266	255,151
2007	34,219	57,336	220,545
2008	31,278	44,074	162,440
2009	8,922	50,717	182,542
Average 2003-2009	21,414	36,434	156,977

Source: NMFS Catch Accounting System. Data compiled by AKFIN, February 2010. Excludes PSC attributed to the State Pacific cod fishery.

Table 8 identifies *C. bairdi* Tanner crab PSC for 2003 through 2009, by gear type, in reporting area 630. Nonpelagic trawling contributes the majority of *C. bairdi* PSC in the Federal groundfish fisheries in 630, ranging from 56 percent to 99 percent from 2003 through 2009, and averaging 83 percent over the time period. In Table 9, a similar estimate of crab PSC mortality by gear type is provided, using an assumed 80 percent mortality rate for trawl gear, and both 20 percent and 50 percent mortality rates for pot gear. Using the 20 percent pot gear mortality rate, nonpelagic trawl vessels are responsible for 95 percent of crab PSC mortality, on average from 2003 through 2009; using the 50 percent mortality rate, nonpelagic trawl vessels are responsible for 88 percent of crab PSC mortality. Table 10 provides some historical context for Tanner crab PSC in the trawl fisheries, for the GOA as a whole, from 1993 through 2002. Groundfish pot gear catches the remainder of Tanner crab PSC, with less than 1 percent of the total attributable to hook-and-line and pelagic trawl gear. Note, this section only reports on the number of crab caught as PSC; the relative impact of PSC on the mortality of crab likely differs by gear type, although studies differ as to the degree (see Section 3.3.2).

⁵ Prohibited species catch (PSC), including catch of *C. bairdi*, is extrapolated to all catch in the GOA groundfish fleet, using specific catch estimation procedures based on observed PSC rates (see further explanation in Section 3.3.1). The observed PSC rate is also applied to Pacific cod catch in the State managed fisheries that base their guideline harvest level on the Federal Pacific cod acceptable biological catch (ABC) level. In order to provide the Council with an estimate of only the PSC taken in Federal fisheries, crab PSC in the State waters pot fisheries was identified, based on the reported date and location of catch. A discussion of the State waters Pacific cod fishery PSC is presented separately in Section 3.4.1.

Table 11 and Figure 19 show the PSC of Tanner crab in proportion with overall groundfish catch for each gear type. In Table 11, the average rate of Tanner crab PSC per mt of groundfish catch for 2003 through 2009 was 2.71 crab per mt of groundfish for the nonpelagic trawl fisheries, and 5.2 crab per mt of groundfish for the pot fishery. When PSC mortality by gear type is taken into account, the rate of mortality averages 2.17 crab per mt of groundfish for nonpelagic trawl fisheries, and either 1.04 or 2.60 crab per mt of groundfish for pot fisheries. Catch of groundfish by pot gear has remained relatively consistent throughout the last five years (Figure 19), while PSC of crab increased in 2007 and 2008. The correlation of nonpelagic trawl PSC and groundfish catch is less consistent over 2003 through 2009, with 2004 and 2008 having low PSC rates, and 2006 having a high PSC rate. It should be remembered when evaluating these PSC numbers that they are extrapolated to the fleet as a whole from PSC recorded on observed vessels, which account, on average, for about one third of groundfish catch in the central GOA.

Table 11 Rate of Tanner crab PSC and mortality per mt of groundfish catch in reporting area 630, by gear type, 2003 through 2009, in Federal groundfish fisheries

The highest numbers of Tanner crab taken as PSC occur primarily in the nonpelagic trawl fisheries targeting flatfish, and in the pot fishery for Pacific cod (Table 12). In the nonpelagic trawl fisheries, the arrowtooth flounder target accounted for 33 to 66 percent of all *C. bairdi* PSC in reporting area 630 (by any gear type) in 2004 through 2006, the shallow-water flatfish target accounted for 30 percent in 2007 and 48 percent in 2003, and the rex sole target accounted for 58 percent of PSC in 2009. Nonpelagic trawl vessels targeting pollock and Pacific cod also contribute to Tanner crab PSC in some years, but always account for less than 10 percent of the gear type’s total Tanner crab PSC, and in the rockfish target fishery was less than 4 percent of the total in 2004 and 2005, and has been very low since the implementation of the rockfish pilot program in 2007. The Pacific cod pot fishery accounted for 20 percent, 27 percent, and 43 percent of all Tanner crab PSC in reporting area 630 in 2005, 2007, and 2008, respectively, but only 1 percent to 8 percent in other years.

Timing of PSC in Federal groundfish fisheries

The majority of Tanner crab PSC is taken in the nonpelagic trawl and pot groundfish fisheries between January 1 and July 31 (Table 13). From 2003 through 2006, between 80 percent and 100 percent of all Tanner crab PSC in the trawl fishery occurred within this season. In 2007 and 2008, approximately two-thirds of trawl Tanner crab PSC occurred in January through July, although in 2009, only one third of occurred during this period. For pot vessels, the proportion of PSC taken in January through July has varied from 59 percent to 100 percent, with an average of 89 percent over 2004 through 2009.

Table 13 Proportion of annual *C. bairdi* Tanner crab PSC taken in January through July in reporting area 630, 2003 through 2009, in GOA Federal groundfish fisheries, by gear type

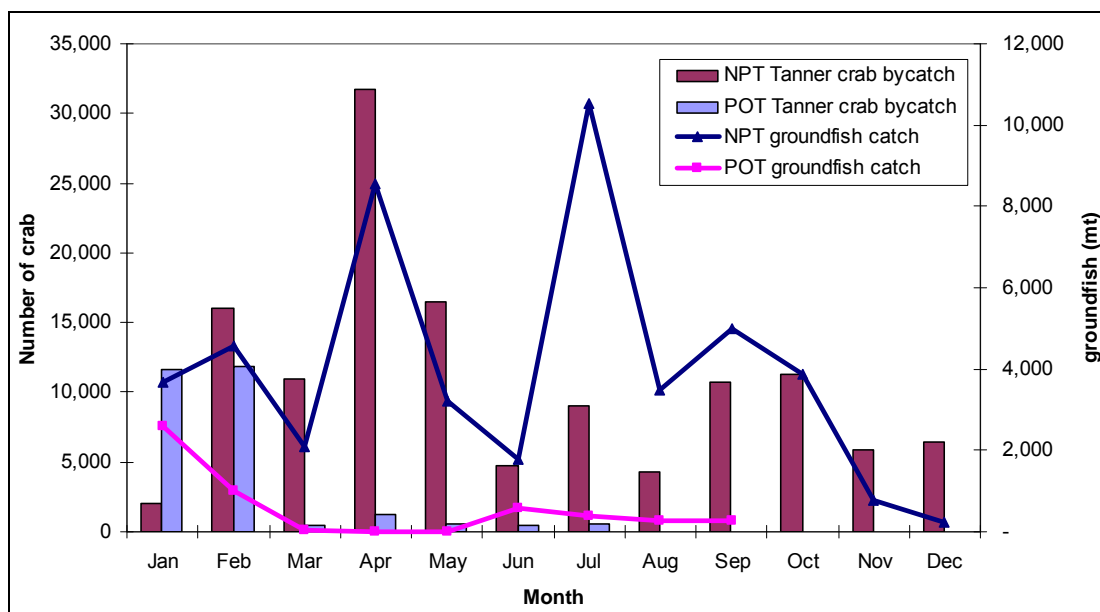

Year	Hook-and-line	Nonpelagic Trawl	Pelagic Trawl	Pot
2003	100%	80%	98%	**
2004	100%	98%	0%	90%
2005	87%	100%	97%	75%

C. bairdi Tanner crab taken in nonpelagic trawl and pot fisheries generally fluctuate temporally, in direct response to groundfish catches (Figure 20). Trawl Pacific cod and flatfish harvests are managed on a quarterly basis, and the trawl fishery begins on January 20th each year. The pot Pacific cod fishery has two seasons (note, the State-managed Pacific cod fishery occurs in the middle of these, beginning in

March, as described further in Section 3.4.1). In the nonpelagic trawl fisheries, average PSC of Tanner crabs from 2003 through 2009 (in numbers of crabs) increased notably in April due to PSC in the combined flatfish fisheries. High groundfish catch by trawl vessels in July is associated with the rockfish fishery, which has lower Tanner crab PSC.

Figure 20 Average PSC of *C. bairdi* Tanner crab and total groundfish catch by month in reporting area 630, for nonpelagic trawl and pot sectors, in Federal fisheries, 2003 through 2009

The implementation of the Central GOA rockfish pilot program, in 2007, has allowed some GOA nonpelagic trawl fisheries to occur later into the year than has been the case in years immediately previous. The rockfish program has allowed fishery participants to reduce their catch of halibut PSC, which in previous years has closed down flatfish trawl fisheries in the GOA. Figure 21 illustrates the weeks in the last quarter of the year during which participants have been active in Central GOA trawl fisheries, primarily for flatfish, from 2000 through 2009. Table 13 identifies that crab PSC in the nonpelagic trawl fisheries in August through December was higher in 2007 through 2009, the years of the program, than in the years immediately previous.

Year	October				November				December

Figure 21 Season duration of the trawl Central Gulf of Alaska groundfish fisheries from October 1 through December 31, 2000 through 2009

3.3.4 PSC in proposed area closures considered in this analysis

The proposed area closures that are considered in this analysis are within the 630 reporting area, described in Section 3.3.3. In order to examine the spatial distribution of PSC at a finer scale than that of the reporting area, it is only possible to use the PSC data collected on observed trips, as only observed hauls are associated with geographical coordinates. Consequently, it is not possible to use the NMFS catch accounting database, which takes PSC reports from observed fishing trips and extrapolates them to apply to all vessels fishing within the reporting area, to investigate the catch and PSC activity of vessels fishing within these specific areas. It is possible to get a sense for how much catch and PSC is occurring in the closed areas, however, by looking at data from observed groundfish vessels, as long as the limitations of using only data from observed vessels are kept in mind. These limitations are discussed in detail in Section 3.3.1. Only vessels that are 60 feet or longer are observed. Vessels between 60 and 125 feet using hook-and-line or trawl gear are only required to carry an observer for 30 percent of their fishing days, by quarter; although if they are larger than 125 feet the must have an observer onboard 100 percent of the time. Pot vessels carry an observer while 30 percent of their pots are pulled for the calendar year. Table 14 shows the number of observed vessels fishing in the proposed area closures over the period 2001 through 2009, compared to the number of vessels fishing in reporting area 630 as a whole. In many of the proposed area closures, the number of vessels of a particular gear type fishing in an area in a particular year may be very small. As a point of comparison, Table 15 shows the number of unique vessels fishing in the proposed area closures that appear in the observer data, and the number of unique vessels that reported on fish tickets that they fished in the statistical areas that approximate the proposed area closures. This comparison is intended to provide some information as to the number of unobserved vessels that may be using the proposed closed areas. However, it should be noted that in some cases (particularly for the Marmot and Chiniak closures), using the statistical areas to approximate the proposed closures may overestimate the number of vessels fishing in those areas. Also, the location information from the fish ticket data is self-reported, and may not always be entirely accurate. From the table, there appear to be many more pot vessels fishing in the proposed closures than is apparent in the observer data (15 vessels were observed, although 62 vessels reported fishing in the areas on fish tickets). For pelagic trawl vessels, approximately two-thirds of all vessels reportedly fishing in the areas have carried observers there at some time, and almost all (60 out of 64) nonpelagic trawl vessels have carried observers to the areas.

Table 14 Number of observed vessels fishing in the proposed area closures, by gear type, for the period 2001 through 2009, and total of all vessels fishing in reporting area 630

Gear type		Observed vessels							Total vessels fishing in 630

Pelagic trawl	Observer data	21	17	16	23	15	23	18	17	13	41
	Fish ticket data	48	29	37	43	32	31	26	28	34	61
Pot	Observer data	2	2	1	4	6	5	3	4	2	15
	Fish ticket data	14	11	8	18	21	28	25	25	23	62

¹For the fish ticket data, proposed closed areas are approximated using the seven statistical areas within which the closed areas occur. In some cases, this may overestimate the number of vessels.

²The location of fishing in a particular statistical area is self-reported on fish tickets.

Table 4 in Section 3.3.1 examines the actual percentages of observed catch by gear type and target fishery. Overall, the pot Pacific cod target had averaged between 12 percent and 26 percent of groundfish catch observed in the Central GOA between 2004 and 2006. Similarly, the nonpelagic trawl shallow-water flatfish fishery averaged between 13 percent and 34 percent of catch observed between 2004 and 2007 in the same area. **Therefore, it should be remembered throughout this discussion that the data do not represent all fishing effort within the closed areas.**

In this section, we report annual observed PSC and groundfish catch in the proposed area closures as a proportion of the total observed effort in reporting area 630. In the figures which illustrate where observed vessels fished, PSC and groundfish catch numbers are summed for all the years from 2001 through 2009.

Observed PSC in area closures, by gear type and target fishery

Tanner crab PSC in the proposed closures, on observed vessels, represents an average of 65 percent of total observed Tanner crab PSC from reporting area 630, for the years 2001 through 2009, across all gear types (Table 16). The majority of PSC comes from ADF&G statistical areas 525702 and 525630, representing approximately 55 percent of the total observed Tanner crab PSC from reporting area 630. The proportion of PSC coming from these areas is fairly consistent across the range of years included in

this analysis, with the exception of 2002 and 2005, when the PSC rate in areas outside of the proposed closure areas represented the majority of Tanner crab PSC in reporting area 630. Figure 22 compares the proportion of observed PSC with the proportion of observed groundfish catch that is attributed to the proposed closure areas, as compared with reporting area 630. The proportion of groundfish catch from the proposed closure areas varies between 16 percent and 30 percent of the total groundfish catch for 630.

Table 16 Observed Tanner crab PSC in the proposed area closures, as a proportion of total observed Tanner crab PSC in reporting area 630, for all gear types

Source: AKFIN Comprehensive Observer data, March 2010.

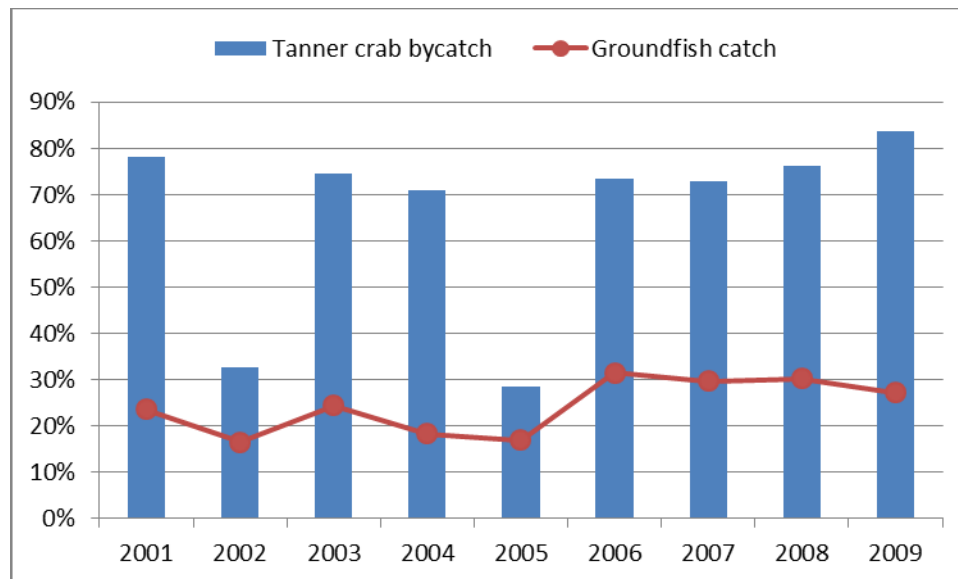

Figure 22 Groundfish catch and Tanner crab PSC in the proposed closed areas, as a proportion of total catch and PSC in reporting area 630

Table 17 combines observer data for the years 2001 through 2009, and identifies the proportion of observed PSC for reporting area 630, for all years combined, that is attributable to each gear type in each of the proposed closure areas. Very few hook-and-line vessels were observed within the closed areas during the 2001 through 2009 period. Pelagic trawl vessels did fish in the closed areas, but contributed

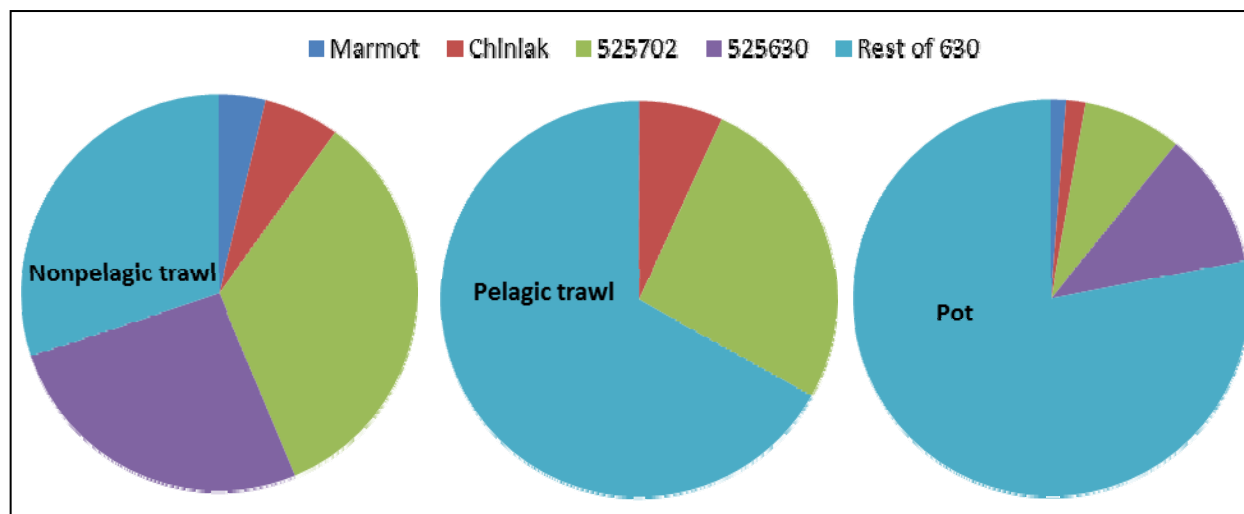

very little to the total observed Tanner crab PSC in all of 630, including in the proposed closure areas. Based on observer data, nonpelagic trawl vessels fishing in the proposed closed areas account for 89 percent of the total Tanner crab PSC observed in 630 across all years combined, with 70 percent of that PSC caught in the proposed closure areas, the majority in statistical areas 525702 and 525630 (Figure 33). For groundfish pot vessels, the majority of observed Tanner crab PSC attributable to the gear type was caught in areas outside of the proposed closures. Table 18 shows observed PSC mortality rates for each gear type, number of dead PSC crab per mt of groundfish, over the same period for inside and outside the proposed area closures and in reporting area 630 as a whole. For all gear types, PSC mortality rates are higher inside the closed areas as a whole than outside, which is consistent with the fact that the closures represent areas with higher crab abundance. For nonpelagic trawl vessels, PSC mortality rates are highest in the Marmot closure, where there is the least observed nonpelagic trawl effort. For pot vessels also, observed groundfish catch is low in all of the closed areas, but the PSC mortality rate is highest in 525630. Only 14 percent of observed groundfish catch by pot vessels in reporting area 630 occurred in the closed areas, compared to 29 percent of catch for nonpelagic trawl vessels, 22 percent of catch for pelagic trawl vessels, and 2 percent of catch for hook-and-line vessels (see Table 34 in Section 6.5.2).

Source: AKFIN Comprehensive Observer data, March 2010.

The targets that have been observed in the proposed area closures are similar to those described for reporting area 630 as a whole. Primary nonpelagic trawl targets are flatfish (mainly arrowtooth flounder and shallow-water flatfish, and some rex sole and flathead sole), with some Pacific cod and pollock targeting. Pelagic trawlers in the area are targeting pollock, and pot vessels Pacific cod.

Timing of observed PSC in proposed closed areas

The majority of Tanner crab PSC in the proposed area closures that are considered in this analysis, and in reporting area 630 as a whole, is caught during the first part of the year. Table 19 identifies the proportion of annual observed PSC caught in each of the proposed area closures, by all gear types, between January 1 and July 31, for the years 2001 through 2009. On average, with the exception of the Chiniak area, between 73 percent and 82 percent of all Tanner crab PSC in the proposed closures occurred in this time period. Table 20 shows the proportion of PSC caught in January through July for each gear type, all years combined. In the Chiniak area, there is a higher occurrence of groundfish fishing in the second half of the year by nonpelagic trawl vessels than occurs in the other proposed closures. Table 21 illustrates how the PSC is proportioned on a monthly basis.

Composition of PSC

The composition of Tanner crab caught and sampled on observed vessels within reporting area 630 was evaluated for 2001 to 2009 (Table 22). Overall, the majority of is comprised of sublegal males (i.e., males less than 140 cm in carapace width), averaging 69 percent of the observed, sampled PSC for 2001 through 2009 (ranging from 54 percent to 85 percent in individual years). Approximately one fifth is mature crab (10 percent legal males and 11 percent female crab with eggs), and an average of 8 percent are females without eggs. The distribution of PSC by sex and size/maturity is fairly consistent by month, although the number of samples is considerably lower in June, August, November, and December.

Table 22 Estimate of PSC composition of Tanner crab for 2001 through 2009, in reporting area 630

Sex		2001	2002	2003	2004	2005	2006	2007	2008	2009	Average 2001-2009
Male	Legal	8%	1%	2%	6%	12%	12%	19%	8%	6%	10%
	Sublegal (<140cm)	60%	68%	68%	85%	80%	74%	54%	77%	66%	69%
Female	Adult (with eggs)	8%	13%	24%	5%	4%	10%	17%	6%	19%	11%
	Sublegal (no eggs)	21%	17%	5%	4%	4%	4%	8%	8%	6%	8%
Unknown		3%	1%	0%	1%	0%	1%	3%	0%	1%	1%
Total number of samples		868	1,176	1,098	524	1,916	1,701	2,336	1,370	470	1,273

Table 23 identifies the PSC composition in the proposed closed areas, compared to the rest of reporting area 630. In general, the composition in the proposed closures that are considered in this analysis is very similar to the overall PSC composition for 630. The Marmot closure shows a slightly higher proportion of females with eggs (19 percent), as does the inshore portion of the Chiniak closure (19 percent in statistical area 525732, compared to 9 percent and 7 percent in the offshore areas 515730 and 515700). Sublegal females are also a higher proportion of PSC in the inshore portion of the Chiniak closure (19 percent).

Table 23 Estimate of average PSC composition of Tanner crab in proposed closure areas, for 2001 through 2009 combined, compared to reporting area 630

Sex		Proposed area closures					Rest of 630	Total in 630
		Marmot ¹	Chiniak ²	525702	525630	Total for closure areas		
Male	Legal	6%	4%	12%	12%	9%	12%	10%
	Sublegal (<140cm)	71%	74%	57%	71%	68%	71%	69%
Female	Adult (with eggs)	19%	10%	12%	10%	12%	11%	11%
	Sublegal (no eggs)	4%	11%	14%	7%	10%	5%	8%
Unknown		0%	1%	4%	0%	2%	0%	1%
Total number of samples		1,007	2,250	2,137	1,384	6,778	4,681	11,459

¹Estimates for the Marmot closure here include samples of all observed PSC in ADF&G statistical areas 525807 and 515802, although in fact the closure would only apply to approximately a quarter of 515802 (see Figure 3).

²Estimates for the Chiniak closure here include samples of all observed PSC in ADF&G statistical areas 525732, 515730, and 515700, although in fact the closure would only apply to parts of those three areas (see Figure 3).

Location of PSC in proposed closed areas

In order to map the location of *C. bairdi* Tanner crab PSC in GOA fisheries, as described above, only data from observed vessels are used, because they are associated with geographical coordinates. The observer program database contains detailed sample-level information on species composition and the results of extrapolations from the sample(s) to the haul level. This spatial analysis uses the haul-level extrapolated PSC numbers of *C. bairdi*, as well as the official weight of the haul, to calculate and present PSC numbers and rates. The distribution of PSC for 2001 through 2009 (summed over those nine years) is mapped using data from the AKFIN Comprehensive Observer database, March 2010.

Color Figure 1 through Color Figure 3, found at the end of this document, map observed Tanner crab PSC and groundfish catch in reporting area 630 for nonpelagic trawl vessels. Color Figure 1 shows the observed number of crab PSC, summed over 2001 through 2009, within 10 km grids. The red squares indicate areas of high PSC, and the green low areas. Note that the northwestern portion of the Chiniak proposed area closure is closed to nonpelagic trawling under the GOA red king crab Type 1 closure, and that part of the western portion of 525702 is closed seasonally as a Type 2 closure (see Section 1 for more information). The southeastern portion of the Chiniak closure has areas of higher PSC, as does the central sections of the 525702 and 525630 closures. PSC in the 525807 closure is comparatively not as high, although directly to the east of the proposed closures are grids with higher PSC.

By comparing Color Figure 1 with Color Figure 2, it is apparent that many of the areas that are subject to high Tanner crab PSC are also areas that are heavily fished by nonpelagic trawl vessels. This is

particularly true for the central sections of 525702 and 525630, and to some extent also for the Chiniak southeastern section. Color Figure 3 demonstrates this comparison by illustrating the amount of groundfish that is caught for each PSC crab. In this figure, grids with a high PSC rates are shown in orange and red. A relationship is apparent between high groundfish effort and higher PSC levels in 525702, 525630, and Chiniak.

The same three types of figures are provided for pelagic trawl and pot vessels. Maps of hook-and-line effort in the proposed closure areas are not included, as there has been very little observed hook-and-line effort in these areas in 2001 through 2009. Color Figure 7 shows the number of crab PSC observed for pelagic trawl vessels, and Color Figure 9 the groundfish catch for the same period. Note that the scales are the same for each gear type for crab PSC and the PSC rate per mt groundfish, however for groundfish effort, the pot gear map (Color Figure 11) has a different scale. Pelagic trawling for pollock, the primary target in these areas, is prohibited in the northeastern portion of the Chiniak proposed closure, due to Steller sea lion protection measures. Color Figure 10 shows the rate of groundfish catch per crab caught as PSC, which identifies the north central portion of 525702 as having a low PSC rate for pelagic trawlers.

The maps for pot effort show that the majority of observed pot fishing does not occur within the proposed closed areas. The highest areas for crab PSC on observed vessels were to the southwest, just outside of 525630 (Color Figure 11), and Color Figure 12 shows that the majority of observed catch in reporting area 630 occurs to the northeast of Kodiak Island. There are pockets of higher PSC in 525702 and 525630, and in the inshore part of the Chiniak proposed closure. Color Figure 13 illustrates PSC rates for observed pot vessels, which are often high, however it should be remembered that studies show that the PSC mortality rate of crab for this gear type is lower than that for trawl gear (Section 3.3.2).

3.4 C. Bairdi Tanner crab PSC in other fisheries

3.4.1 PSC of *C. bairdi* in the State waters Pacific cod pot fishery

The State-managed Pacific cod fishery in western and Central GOA began in 1997, and is only open to pot and jig gear. The fishery is managed in five districts: South Alaska Peninsula, Chignik, Kodiak, Cook Inlet, and Prince William Sound. The State bases its guideline harvest level on the Federal acceptable biological catch (ABC) for Pacific cod, and the Council and NMFS reduce the Federal total allowable catch (TAC) for Pacific cod to accommodate the State fishery. In most cases, the fisheries open one week after the close of the Federal Pacific cod A season, and occur in late February to April.

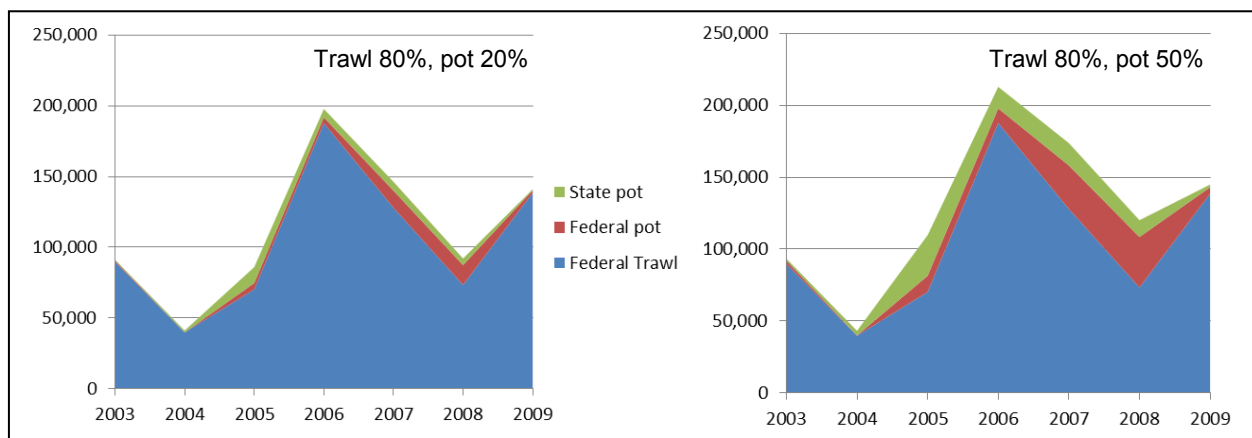

In the discussion of PSC numbers in Sections 3.3.3 and 3.3.4, catch amounts attributable to the State Pacific cod fishery are not included in the data. However, NMFS inseason management tracks the catch of Pacific cod in the State water fishery, and also makes PSC extrapolations based on that groundfish catch. Since there is no observer coverage in the State Pacific cod fishery, NMFS uses observer information from the Federal fishery to estimate PSC in the State fishery. Consequently, these estimates should be interpreted with caution.

Crab PSC from the State Pacific cod fishery was identified based on the date and location of catch and these data are separately in this section. Table 24 identifies the *C. bairdi* PSC attributable to the State managed Pacific cod pot fishery, which varied from a low of approximately 2,750 crab in 2003, to a high of 56,436 crab in 2005. The contribution of the State managed fishery to overall *C. bairdi* PSC in the GOA ranged from a low of 2 percent, in 2003, to a high of 34 percent, in 2005. On average, the State Pacific cod fishery contributes approximately 12 percent to the overall *C. bairdi* PSC in reporting area 630 (Figure 24).

Table 24 *C. bairdi* PSC in Federal and State pot and trawl fisheries in reporting area 630, 2003 through 2009

	Federal trawl fisheries	Federal pot fishery	State Pacific cod fishery (pot gear)	Grand Total	State as % of total
2003	112,237	4,557	2,751	119,545	2%
2004	49,781	434	6,355	56,571	11%
2005	87,788	22,535	56,436	166,760	34%
2006	234,620	20,356	29,894	284,870	10%
2007	159,921	60,507	31,057	251,485	12%
2008	91,727	70,182	23,319	185,227	13%
2009	173,067	9,118	3,751	185,937	2%
Average 2003-2009	129,877	26,813	21,938	178,628	12%

Figure 24 Federal and State *C. bairdi* Tanner crab PSC mortality in GOA groundfish fisheries

3.4.2 Scallop fishery

The Scallop FMP does not include provisions defining “prohibited species,” thus the distinction made under the Groundfish FMPs between bycatch and PSC does not carry over to this (or other) nongroundfish FMPs regulating the BSAI and GOA. Tanner crab are caught in the scallop dredge fishery. Bycatch is controlled through the use of crab bycatch limits (CBLs), which are based on the condition of individual crab stocks. CBLs were first instituted by the State of Alaska in July 1993. In the scallop fishery’s Kodiak Northeast District⁶, in which the proposed area closures are located, CBLs for Tanner crab are set at 0.5 percent or 1.0 percent of the total crab stock abundance estimate, based on most recent survey data. When Tanner crab abundance is sufficient to support a commercial crab fishery, the cap is set at 1.0 percent of the most recent abundance estimate; when Tanner crab abundance is insufficient to support a commercial crab fishery, the CBL is set at 0.5 percent. Bycatch caps are expressed in number of crabs and include all sizes of crabs caught in the scallop fishery. Table 25 lists the CBLs in the scallop fishery from 2000/01 through 2008/09, as well as the estimated bycatch. State managers also have

⁶ Note, the Kodiak Northeast District for scallop management has different boundaries than the northeast section of the Kodiak District for management of Tanner crab. The scallop Kodiak Northeast District includes all waters around Kodiak except in the Shelikof Straits.

inseason authority to close the scallop fishery out of specific areas within the Kodiak Northeast District to address crab bycatch. This might occur if the overall crab survey abundance in an area is low or if the proportion of juveniles to legal males observed as bycatch is high (N. Sagalkin, pers. comm., 2/1/10).

Table 25 C. bairdi Tanner crab bycatch limits and estimated bycatch in the scallop fishery in Kodiak Northeast District, 2000/01 through 2008/09, in numbers of animals

Year	Crab bycatch limit	Estimated bycatch
2000/01	81,000	13,311

3.5 C. bairdi Tanner crab directed fisheries

The Tanner crab fishery in the Kodiak District began in 1967, when 110,961 pounds were landed. The fishery quickly expanded and over 34 million pounds were harvested from 1968 through the 1971/72 season. In response to increased demand and larger harvests, ADF&G initiated a pot survey in 1973 to estimate relative abundance, predict recruitment trends, and develop annual harvest levels. The fishery continued to grow, with annual harvests increasing to a peak of 33 million pounds in the late-1970s. ADF&G implemented an April 30 season closure date in 1975 to protect crab at the onset of the mating and molting season. A minimum carapace width (CW) of 5.5 inches was additionally established in 1976. In the early 1980s, Tanner crab stocks and commercial harvests began to decline, and by the early 1990s, annual harvests averaged less than two million pounds. The fishery was closed for the 1994/95 season, and remained closed until the 2000/01 season. During the six-year closure, a harvest strategy was developed by ADF&G and adopted by the Alaska Board of Fisheries (BOF) in 1999. This harvest strategy has a number of conservation measures to help sustain the Tanner crab population, as well as a number of provisions to slow the pace of the directed fishery. The plan has minimum population levels (biological thresholds) and minimum guideline harvest levels (management thresholds) to open a commercial fishery. Each section must have a GHF of at least 100,000 pounds and the entire district GHF must be at least 400,000 pounds to open. In order to slow the pace of the fishery, fishing is restricted to daylight hours; gear may only be operated from 8:00 AM to 5:59 PM, although gear may be left to soak from 6:00 PM until 7:59 AM. The fishery also has pot limits. Vessels are restricted to 20 pots until harvest levels exceed 2 million pounds, and from 2 million pounds to 4 million pounds the pot limit is 30 per vessel. The Kodiak District is designated superexclusive, which means vessels may not participate in any other Tanner crab fishery in the same calendar year. The number of permits is limited through the limited entry program to approximately 180 permits; although in recent years actual participation has been much lower.

In addition to the mandatory escape mechanism (“bio-twine”), pots are also required to have either 4 escape rings or one third of one vertical surface composed of 7 ¼ inch stretch mesh webbing. Escape rings (or escape mesh) have been shown to reduce the amount of sub legal and female Tanner crab retained in the pot (Pengilly 2000). Vessels must register for individual sections so that ADF&G can track effort and harvest. Most of the fleet participates in a voluntary reporting program where vessels are

contacted on a daily basis for information on harvest, effort, and CPUE. This voluntary reporting is the primary method ADF&G uses to manage the fishery. The distribution of the harvest generally matches stock distributions observed on the trawl survey, and ADF&G closes waters to fishing when inseason targets are achieved. At times, ADF&G will keep areas of a section closed for protection. For example, in 2010, Danger Bay in the Northeast Section was kept closed, because during the survey the population of crab was determined to be very low. Ugak Bay in the Eastside Section was also kept closed. While there was a fishable population of legal crab in Ugak Bay, the proportion of legal males to sublegal males was high, and ADF&G kept the bay closed to minimize sorting (and associated injury and mortality on sub-legal crab).

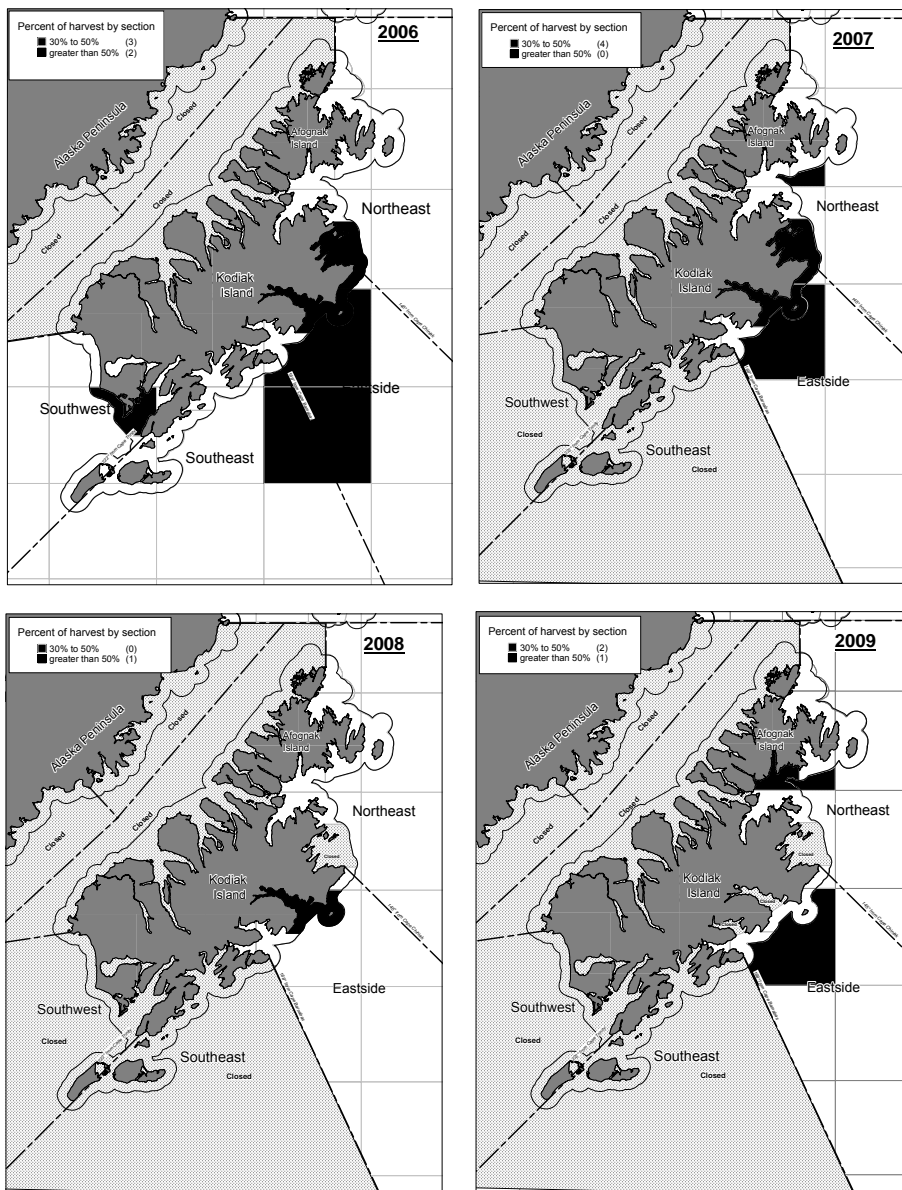

Since adoption of the Tanner crab management plan in 2001, only the Northeast, Eastside, Southeast, and Southwest sections have opened to commercial fishing. The majority of the harvest has occurred in the Eastside Section. Total Kodiak District harvests from 2003 through 2009 have averaged just under a million pounds, and harvests from the Eastside Section over the same time span have averaged approximately 500,000 pounds (232,602 crab).

Figure 25 depicts sections that opened to commercial fishing from 2006 through 2009, and ADF&G statistical areas within those sections where the majority of the harvest has occurred.

Figure 25 Statistical areas where 30 to 50 percent of the harvest occurred and locations where greater than 50 percent of the harvest occurred, 2006 through 2009

Because harvest is documented at the statistical area level, it is difficult to apportion harvest on a smaller scale. In order to analyze fishing locations on a smaller scale, interview data from 2006 through 2009 were aggregated (to maintain confidentiality) and plotted in relation to the proposed closure areas (Figure 26).

3.6 Modified gear to reduce impacts on crab

3.6.1 Sweep modification for bottom trawl vessels

The predominant direct effects caused by nonpelagic trawling include smoothing of sediments, moving and turning of rocks and boulders, resuspension and mixing of sediments, removal of seagrasses, damage to corals, and damage or removal of epibenthic organisms. Trawls affect the seafloor through contact of the doors and sweeps, footropes and footrope gear, and the net sweeping along the seafloor. A considerable proportion of the area adversely impacted by trawling is due to contact between the seafloor and the sweeps.

The process for implementing the sweep modification in the Bering Sea required extensive testing and discussion between the industry and NMFS, in order to identify in regulation a configuration of the gear that was both practicable and enforceable. It is anticipated that a similar discussion would be needed to implement such a gear modification on GOA trawl vessels, in order to determine the optimum configuration, as the class of vessels participating in the two management areas differs (in the Bering Sea flatfish fishery, trawl vessels are primarily catcher processors; there are more smaller trawl catcher vessels operating in the GOA. Further research was conducted in 2011 in the GOA to identify the

appropriate standards for the elevated trawl sweeps to meet the Council’s desired performance standard, and to identify and resolve any implementation issues. Field testing of the modified gear demonstrated that the elevated trawl sweeps can meet the standards adopted for the BS flatfish fishery and can be used in the Central GOA flatfish fishery.

Amendment 94 (75 FR 61642, October 6, 2010) implemented the use elevated sweeps in the BS flatfish fisheries. Trawl sweeps used for all flatfish fishing using nonpelagic trawl gear must install elevating devices (Figure 27) on the sweeps and regular intervals, in order to raise the sweeps off the seafloor and reduce injury and mortality and adverse impacts on benthic habitat. For most Bering Sea flatfish trawls, sweeps are so long (up to 1,500 feet) that they sweep 90 percent of the area covered between the trawl doors. The modifications elevate most of the sweep area 2 to 3 inches above the substrate, allowing space for animals to pass beneath. Studies in the BS have shown that elevating the trawl sweep can reduce trawl sweep impacts effects on *C. bairdi*, *C. opilio*, and red king crabs by reducing the unobserved mortality of these species. In addition, elevating the trawl sweep can reduce impacts on benthic organisms, such as basketstars and sea whips.

In April 2012, the Council recommended vessels using nonpelagic trawl gear to target flatfish in the Central GOA use approved modified gear to reduce the potential adverse effects of nonpelagic trawl gear on benthic habitat and to reduce unobserved Tanner crab injury and mortality. In the GOA, fishing for flatfish includes vessels targeting shallow-water flatfish, deep-water flatfish, arrowtooth flounder, rex sole, and flathead sole. These species and species groups are defined in the annual groundfish harvest specification proposed and final rules each year. Area closures to the use of nonpelagic trawl gear and gear modification on nonpelagic trawl gear used to target flatfish in the Central GOA combined form a suite of management measures recommended by the Council intended to reduce injury and mortality, both observed and unobserved, of Tanner crab and to reduce the potential adverse effects of nonpelagic trawl gear on benthic habitat.

10 inch elevating bobbin connected to 2 inch (52 mm) combination wire with hammerlocks (coupling links).

8 inch elevating discs mounted on body of 2 inch (52-mm) combination wire with stopper swages each side.

Effects on Crab Mortality

In the summer of 2008, researchers conducted a study in the Bering Sea, funded by the North Pacific Research Board, to estimate the mortality rates for snow and Tanner crabs that encounter bottom trawls, but remain on the seafloor. That study estimated mortalities for both species for conventional and modified sweeps. Briefly, crabs were captured by auxiliary nets fished behind different parts of a commercial bottom trawl. They were carefully brought aboard and assessed using a six part reflex test. A

subsample of those crabs was held for 5 to 12 days to establish the relation between reflex state and delayed mortalities. The proportions of crabs in different reflex states and the reflex-mortality relationship were used to estimate raw mortality rates for crabs encountering each part of the trawl. Results for crabs captured with a control net, fished in front of the trawl to serve as a scientific control for the effects of the recapture net itself, were used to assess and adjust for mortalities due to capture and handling. Sample sizes were 21 tows for conventional and modified sweeps and 19 tows of the control net.

Estimates of mortality for crabs encountering conventional sweeps were approximately 5 percent for both species (Figure 28). Mortality rates dropped to nearly zero for crab encountering the modified sweeps. Significance levels for these decreases (conventional versus modified) were 0.002 for *C. bairdi* and <0.001 for *C. opilio*. While overall crab mortality varied significantly by sex and size after gear effects had been accounted for, there were no significant interactions between these factors and gear effects. Thus, the mortality reduction due to the sweep modification persisted across sizes and sexes.

A similar study, also funded by the North Pacific Research Board, was conducted in summer of 2009 in Bristol Bay to estimate mortality rates for red king crab encountering bottom trawls. Results indicate a similar trend in reduced mortality rates for king crab encountering the modified sweeps. The demonstrated reductions in mortality to crabs likely indicate that any mortality of other, smaller epibenthos (such as other crab, sea stars, or shrimp) would also be reduced.

Figure 28 Estimated mortalities of *Chionoecetes opilio*, *C. bairdi*, and red king crab after contact with conventional and modified sweeps. Rates have been adjusted for handling mortality based on mortality estimates from a control net. (Apparent negative mortality is a non-significant artifact of the control adjustment).

Overall, the trawl sweep modification has been tested to be effective in the Bering Sea flatfish trawl fishery in reducing trawl sweep impact effects on *C. bairdi*, *C. opilio*, and red king crabs by reducing the unobserved mortality of these species. Additionally, the trawl sweep modification has proven effective on the Bering Sea shelf at reducing effects on sea whips (a long-lived species of primary concern), and did not substantially reduce catches of target flatfish. Tests for reduced impacts on basketstars, sponges, and polychaete siphons were positive in direction, but non-significant.

The relevance of that study to crabs in the GOA depends largely on the similarities in sediment type in the Bering Sea and GOA, and between the bottom trawl gear tested in the Bering Sea and those used in the GOA. The sediment in the Bering Sea where the flatfish fishery occurs consists mainly of sand, muddy sand, or gravelly muddy sand (NMFS 2009), and such was the sediment in the areas of the research study. As can be seen in Figure 9, sediment in the proposed closure areas is variable, with similar sand and gravelly sand substrates, but also gravelly mud and silty clay areas.

With respect to gear type, AGDB distributed a survey form to their members describing the most relevant characteristics of the trawl gear used in GOA bottom trawl fisheries. RACE Division scientists compiled and summarized the data from the returned survey forms. Fourteen vessels responded to the survey, describing 22 nets used to target flatfish. The survey indicated that GOA bottom trawl gear used to target flatfish in the GOA is similar to that used in the Bering Sea, including the gear used in the research project. It consists of bottom trawls with footropes equipped with large diameter bobbins or disks. Most of the area affected by these trawls is covered by sweeps, long cables between the trawl doors and the net, that herd flatfish into the path of the capture net. The differences in the gear used in the GOA included:

- 1) Most of the GOA trawlers reported diameters of footrope bobbins from 16 to 18 inches diameter in the center and 14 to 16 inches in the wings (sides of the trawl footrope) while Bering Sea trawlers use footrope bobbins and disks from 18 to 23 inches in diameter .
- 2) Most GOA sweeps used 3 inch diameter rubber disks strung over a steel cable instead of the 2 inch diameter combination rope (polyethylene-wrapped steel) used in the Bering Sea fisheries and tests. The rubber disk gear has a rougher surface than the combination rope, but more surface area over which to spread the cable weight. Some GOA vessels reported using combination rope. Some also reported using widely spaced (90 feet to 120 feet) devices that raised the sweeps above the seafloor, similar to the modified sweeps identified in the research.
- 3) Finally, GOA vessels used shorter sweeps than those used by the larger Bering Sea trawlers. While Bering Sea sweeps cover approximately 90 percent of the area affected by their trawls, similar calculations for GOA gear yield 75 percent.

The general similarity of GOA trawl gear to that used in the Bering Sea tests indicates that the results of those tests should approximate mortality rates in GOA fisheries. The smaller area swept by the sweeps in the GOA indicates that the benefits of sweep modifications would be somewhat smaller than those for Bering Sea fisheries, but still substantial. Additional research would be useful to document the effects of the somewhat smaller diameters of footrope components and the differences in sweep materials and diameter.

3.6.2 Pot escape mechanisms

The typical Pacific cod pot has tunnels on three sides with cod triggers that allow the passage and retention of Pacific cod. These tunnels with triggers are normally fixed via webbing to a set of web bars that are inset from the outside frame bars by approximately 2 inches. Crab below a threshold size are also able to enter the pot through the triggers, resulting in Tanner crab PSC when fishing in areas having concentrations of both Pacific cod and Tanner crab. To reduce the crab PSC, a pot would need an opening that would permit crab to exit, while retaining Pacific cod. The prototype pots are identical to the normal pots (overall dimensions: 6 ½ feet x 7 feet x 3 feet) with tunnels on three sides and an access door on the fourth side (Pikus personal communication). On the rear side of the pot (opposite the door), two web bars are placed horizontally across the bottom instead of the usual one, with the tunnel web laced to only the top bar (Figure 29). Vertical bars are then placed in between the two web bars resulting in four escape

openings that are 15 inches wide and 3 inches high. These openings are large enough to permit a Tanner crab to escape, but are not high enough to allow Pacific cod to escape.

4 Probable Environmental Impacts

This document analyzes four alternatives that evaluate proposed area closures to protect *C. bairdi* crab around Kodiak Island. Included in the alternatives are options to select among four proposed areas, and to apply the closures year round or seasonally, and to pot and/or trawl gear types. Additionally, some vessels may be exempted from the area closures, if they meet specific conditions such as using approved gear modifications or an observer coverage requirement.

The proposed action affects vessels fishing in the Federal groundfish fishery in the Central Gulf of Alaska. Only those environmental components that occur in the proposed area closures around Kodiak Island, or in adjacent areas in which displaced vessels may choose to fish, are likely to be affected by this action. These components include crab species, especially *C. bairdi* crab, target and nontarget fish species, marine mammals and seabirds, bottom habitat, and ecosystem components. This environmental assessment focuses on these potentially affected components, and no effects are expected on the other components of the marine environment in the Gulf of Alaska.

In this section, the impacts of the alternatives and option on the various environmental components are evaluated. Section 4.1 addresses the impacts of the alternatives on *C. bairdi* crab. Sections 4.1, 4.2, and 4.5 look at impacts on other crab and fish species and Section 4.3 addresses seabirds and marine mammals. Sections 4.4 and 4.5 address impacts on habitat and the ecosystem, respectively. There are no known significant scientific, historical, or cultural resources in the proposed action area, with the exception of shipwrecks. Shipwrecks are identified on nautical charts used by fishers and are avoided to protect their gear. This action would have no impact on the fishers' avoidance of these sites. The socio-economic impacts of this action are described in detail in the RIR and IRFA portions of this analysis (Sections 6.5.4 and 7.8).

Analysis of the potential cumulative effects of a proposed action and its alternatives is a requirement of NEPA. An environmental assessment or environmental impact statement must consider cumulative effects when determining whether an action significantly affects environmental quality. The Council on Environmental Quality (CEQ) regulations for implementing NEPA define cumulative effects as:

“the impact on the environment, which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time” (40 CFR 1508.7).

For the most part, the discussion of past and present cumulative effects is addressed with the analysis of direct and indirect impacts for each resource component below. The cumulative impact of reasonable foreseeable future actions is addressed in Section 4.6.

Section 5 addresses the management and enforcement considerations of the proposed alternatives and options.

The criteria listed in

Table 27 are used to evaluate the significance of impacts. If significant impacts are likely to occur, preparation of an Environmental Impact Statement (EIS) is required. Although economic and socioeconomic impacts must be evaluated, such impacts by themselves are not sufficient to require the preparation of an EIS (see 40 CFR 1508.14).

Table 27 Criteria used to evaluate the alternatives

Component	Criteria
Fish/crab species	An effect is considered to be significant if it can be reasonably expected to jeopardize the sustainability of the species or species group.
Habitat	An effect is considered to be significant if it exceeds a threshold of more than minimal and not temporary disturbance to habitat.
Seabirds and marine mammals	An effect is considered to be significant if it can be reasonably expected to alter the population trend outside the range of natural variation.
Ecosystem	An effect is considered to be significant if it produces population-level impacts for marine species, or changes community- or ecosystem-level attributes beyond the range of natural variability for the ecosystem.

4.1 *C. bairdi* Tanner crab

A discussion of crab stock abundance and PSC in the groundfish fisheries, both inside and outside of the proposed closed areas, is addressed in Chapter 3 and Section 4.2. This section draws on this information to evaluate the effects of the alternatives and options.

Alternative 1 – status quo

As described in Section 3.2, ADF&G conducts annual surveys of the crab stocks in the GOA (Spalinger 2010). The surveys are partial, and concentrate on the historically most important areas of crab abundance; however, the estimates of abundance are on the low side of total abundance in the area since the total crab habitat is only partially surveyed. In 2009, the estimate of Tanner crab in the Kodiak District was approximately 84 million animals (Table 1). The estimated PSC in 2009 in the groundfish fisheries for reporting area 630 was approximately 183,000 animals (Table 7 in Section 3.3.3); combined for areas 620 and 630, estimated PSC was 223,000 animals (although area 620 also includes the Tanner crab Chignik district population). In either case, this represents approximately 0.2 percent of the surveyed abundance of the Kodiak District. The proportion is also comparable for the 2003 through 2009 averages for groundfish Tanner crab PSC and Kodiak District Tanner crab surveyed abundance. Approximately two-thirds of the PSC is composed of sublegal males (Table 22). State crab fishery managers have identified the Eastside Section of the Kodiak District as the most important area for the Tanner crab population (N. Sagalkin, pers. comm., 2/1/10). This area contains most of the biomass for the District (an average of 44 percent of abundance for the period 2003 through 2009; Table 1). PSC information for the groundfish fishery as a whole is available for reporting area 630, which is larger than the Eastside Section, including most of the Kodiak District Sections excepting Southwest and South Mainland. However, observer data shows that Tanner crab PSC in the Eastside Section (represented by PSC in proposed area closures 525702 and 525630) was approximately 70 percent of total observed PSC in 630 in 2009, and 55 percent on average from 2001 through 2009. The total Tanner crab PSC by the groundfish fisheries in reporting area 630 represents 0.5 percent of the surveyed crab abundance in the Eastside Section for 2009, or 0.3 percent of the average abundance for 2003 through 2009. To provide some context for this percentage, the State of Alaska has set crab PSC limits for the scallop fishery at 0.5 percent to 1 percent of the total crab stock abundance for the Kodiak area (however, the scallop fishery is also 100 percent observed, and PSC numbers for that fishery are more reliable than is the case for the groundfish fishery).

Additionally, Sections 3.1 and 3.5 describe that the Tanner crab population around Kodiak has been rebounding from lows in the mid-1990s, despite continued PSC in the groundfish fisheries throughout this period (Table 12). Since 2000/01, crab abundance has met the minimum population levels to support a commercial fishery. Overall abundance since that time has been variable, with peaks in 2001 and 2006 through 2007 (Table 1). Consequently, based on the criteria identified in Table 27, groundfish PSC

impacts on the sustainability of Tanner crab in the Kodiak District are considered as adverse, but are not expected to be significant.

Alternative 2 – close areas to groundfish fishing

Closing specific areas to groundfish fishing in order to reduce Tanner crab PSC is likely to benefit the stock by reducing a source of both observed and unobserved mortality. The proposed area closures account for an average of 65 percent of the total observed Tanner crab PSC in the groundfish fisheries for 2001 through 2009, while only representing an average of 25 percent of groundfish catch (Table 16 and Figure 22). Consequently, groundfish effort that is displaced into neighboring areas is not likely to have as high a PSC of Tanner crab as is currently occurring in the proposed closed areas. Section 4.2 examines potential environmental impacts on Tanner crab and groundfish within the context of the ecosystem and concludes that the largest change in Tanner crab biomass due to the most extreme scenario (where effort in flatfish, pollock, and cod trawl fisheries were all reduced by the maximum expected amount simultaneously) was most likely to range from no change to a 9 percent reduction from the base scenario. While overall impacts to Tanner crab stocks are not expected to be significantly beneficial, the localized benefits within the proposed closure area is expected to be beneficial towards the conservation and protection of Tanner crab and may improve opportunities for the directed Tanner crab fishery in the proposed closure area.

Suboptions 1, 2, 4, 5 – close areas to a particular gear type

Nonpelagic trawl gear catches the vast majority of Tanner crab PSC in reporting area 630 (Table 8), in part because this gear type also accounts for approximately 60 percent of total groundfish catch in the area. PSC mortality rates are higher in the proposed area closures, based on observer data, 3.39 crab/mt groundfish compared to 0.59 crab/mt groundfish in the rest of 630 (Table 18). Based on observer data, PSC is highest in 525702 and 525630 (the areas with the highest Tanner crab population), and lower in the Chiniak and Marmot areas (which have lower abundance of Tanner crab) (Color Figure 1). Fishing effort is also highest in the Eastside Section closures (525702 and 525630; Color Figure 2). Displaced vessels may have a lower catch per unit effort from harvesting groundfish in neighboring, less productive areas; this may increase the Tanner crab PSC in these neighboring areas. However, overall the implementation of the area closures for nonpelagic trawl vessels is likely to reduce Tanner crab PSC overall, and as such would benefit the stock.

Pot vessels account for an average of 17 percent of Tanner crab PSC in reporting area 630 (Table 8), although in terms of mortality, pot vessels account for either 5 percent or 11 percent of the total, depending on the rate used (Table 9). According to the observer data, the proposed area closures are not used extensively by pot vessels; most of the observed pot effort occurs elsewhere, and Tanner crab PSC is highest for pot vessels in areas outside of the proposed area closures (Color Figure 11 and Color Figure 12). The limitations of observer coverage should be remembered for this sector, as observed trips are fewer, both due to the size of vessels in the fleet and the overall amount of groundfish catch by this sector. Observer data would indicate that the area closures that are proposed in this analysis are not optimally designed for reducing crab PSC in the pot sector; however, to the extent that pot vessels are currently fishing in the proposed closure areas, the crab stocks will benefit from the reduced PSC.

Pelagic trawl vessels use the proposed closed areas for pollock fishing, according to data from observed vessels, but also have very low Tanner crab PSC, both in the proposed closed areas and in reporting area 630 as a whole. The benefit to Tanner crab stocks of closing the proposed areas to pelagic trawling would be slight.

Suboption 3 – exempt vessels using approved, modified gear from area closures

Section 3.6 discussed two types of modified gear that might be used in the groundfish fisheries to reduce crab PSC; however, neither has been tested for use in the GOA. The trawl sweep modification has proven to be effective in the Bering Sea flatfish fisheries, and in that instance is successful at reducing unobserved mortality of crab from the trawl sweeps. While requiring this modification for vessels fishing in the area closure could certainly provide benefit to crab stocks, by reducing unobserved mortality, it would not be likely to change reported PSC totals from trawl fishing, which account only for PSC that comes up in the trawl net. It is not possible to quantify any benefit to crab stocks in the GOA without further testing to understand how sediment conditions in the area closures compare to the areas in which Bering Sea experiments occurred. However, the general similarity of GOA trawl gear to that used in the Bering Sea indicates that while the benefits may be smaller, they could still be substantial.

Amendment 94 (75 FR 61642, October 6, 2010) implemented the use elevated sweeps in the BS flatfish fisheries. Trawl sweeps used for all flatfish fishing using nonpelagic trawl gear must install elevating devices (Figure 27) on the sweeps and regular intervals, in order to raise the sweeps off the seafloor and reduce injury and mortality and adverse impacts on benthic habitat. For most Bering Sea flatfish trawls, sweeps are so long (up to 1500 feet) that they sweep 90 percent of the area covered between the trawl doors. The modifications elevate most of the sweep area 2 to 3 inches above the substrate, allowing space for animals to pass beneath. Studies in the BS have shown that elevating the trawl sweep can reduce trawl sweep impacts effects on *C. bairdi*, *C. opilio* and red king crabs by reducing the unobserved mortality of these species. In addition, elevating the trawl sweep can reduce impacts on benthic organisms, such as basketstars and sea whips.

In April 2012, the Council recommended vessels using nonpelagic trawl gear to target flatfish in the Central GOA use approved modified gear to reduce the potential adverse effects of nonpelagic trawl gear on benthic habitat and to reduce unobserved Tanner crab injury and mortality. In the GOA, fishing for flatfish includes vessels targeting shallow-water flatfish, deep-water flatfish, arrowtooth flounder, rex sole, and flathead sole. These species and species groups are defined in the annual groundfish harvest specification proposed and final rules each year. Area closures to the use of nonpelagic trawl gear and gear modification on nonpelagic trawl gear used to target flatfish in the Central GOA combined form a suite of management measures recommended by the Council intended to reduce injury and mortality, both observed and unobserved, of Tanner crab and to reduce the potential adverse effects of nonpelagic trawl gear on benthic habitat.

The pot modification has not yet been tested at all. Should it prove effective, it would successfully reduce PSC for the Pacific cod pot fishery. As there are currently no test results available, it is, however, unknown what the impact will be on crab stocks.

Option 1 or 2 – close areas either year round or seasonally

As described in Section 3.2.2, crab are most vulnerable during mating, molting, and hatching. Table 3 shows the annual timing for these activities for Tanner crab. April and May appear to be key months during which crab are sensitive, although the timing of the female molt to maturity spans a longer timeframe. The directed crab fishery is closed from April 30, in order to protect crab at the onset of the mating and molting season.

Option 1, the year round closure, would provide the most protection to Tanner crab. However, Table 13 illustrates that on average, 70 percent to 90 percent of Tanner crab PSC in the groundfish fisheries (for reporting area 630) is taken with the January through July period (i.e., the proposed closure interval under Option 2), so that under Option 2, crab stocks would still receive some level of benefit from the seasonal closure. The January through July period would encompass the most sensitive months of the crab mating and molting cycle. Using observer data to look specifically at the proposed area closures, the pattern is

similar for most of the areas except for Chiniak. In that case, only half of the average PSC is caught during the January through July period, as more groundfish fishing occurs in this area in the latter part of the year.

Alternative 3 – close areas to groundfish fishing unless vessels using trawl gear have 100 percent observer coverage and vessels using pot gear have 30 percent coverage

Alternative 3 would not provide additional protection to crab for those vessels that take advantage of the exemption and fish with 100 percent observer coverage for vessels using trawl gear and 30 percent observer coverage for vessels using pot gear. For vessels electing not to take the additional observer coverage to fish in the areas, the impact would be similar to Alternative 2. The primary benefit of Alternative 3 would be to reduce the uncertainty associated with the reported PSC numbers for vessels using trawl gear fishing in the proposed closure areas, as all fishing in the areas would be fully monitored. Alternative 3 also would increase observer coverage for any vessel less than 60 feet length overall using pot gear, as these vessels currently are not required to carry observers. Some additional information also may be gathered from vessels 60 feet and greater LOA using pot gear. Although these vessels currently are required to have 30 percent observer coverage, the additional requirement that observer coverage obtained inside the closure areas could not be used to count towards the vessels' 30 percent observer coverage outside of the closure areas would increase the amount of observer data for pot fishing within the closure areas.

PREFERRED ALTERNATIVE – close the Marmot Bay area (statistical area 525807) year-round to nonpelagic trawl fishing, and require pot vessels fishing in the area to have 30 percent observer coverage. Close the Chiniak Gully and 525630 areas to trawl and pot fishing, unless vessels have 100 percent and 30 percent observer coverage, respectively.

The Preferred Alternative falls within the range of Alternatives 2 and 3, and combines elements of both, resulting in impacts that fall with the range of Alternatives 2 and 3. Under the Preferred Alternative, a single area defined in Alternative 2, the Marmot Bay statistical area 525807, would be closed year-round to nonpelagic trawl fishing. The year round closure would provide the most protection to Tanner crab. Additionally, state waters to the north and west of the proposed Marmot Bay area and Federal waters to the south of the area are closed to the use of nonpelagic trawl gear year round. The Marmot Bay area had the highest observed PSC mortality rate of Tanner crab for nonpelagic trawl vessels (7.68 crab per mt of groundfish catch, for the combined years 2001 through 2009; Table 18). The nonpelagic trawl gear sectors observed Tanner crab PSC in the area accounted for an average of 4 percent of the total observed Tanner crab PSC in the groundfish fisheries for 2001 through 2009 (Table 17), while only representing an average 3 percent of groundfish catch (Figure 22). Consequently, there is unlikely to be a large displacement of groundfish effort into neighboring areas. The area closure to trawl gear, except vessels using pelagic trawl gear to target pollock, will reduce Tanner crab PSC, although only by a small percentage of the total Tanner crab PSC in groundfish fisheries. While overall impacts to Tanner crab stocks are not expected to be significantly beneficial, the localized benefits within the proposed closure area is expected to be beneficial towards the conservation and protection of Tanner crab and may improve opportunities for the directed Tanner crab fishery in the proposed closure area.

As with Alternative 3, the Preferred Alternative establishes areas that would be closed to nonpelagic trawl and pot fishing unless a vessels has 100 percent or 30 percent observer coverage, respectively. The Preferred Alternative creates crab protection areas in Chiniak Gully and 525630, which will be closed to both nonpelagic trawl and pot vessels unless vessels carry observer coverage. Additionally, pot vessels may only fish in the Marmot Bay closure (statistical area 525807) if they have 30 percent observer coverage. Unlike Alternative 3, no closure is established in the Preferred Alternative for statistical area 525630. The primary benefit of this component of the Preferred Alternative would be to reduce the uncertainty associated with the reported crab PSC amounts for vessels using nonpelagic trawl and pot gear fishing in the proposed areas, as all fishing in the areas would be fully monitored. This would allow

the Council, at some time in the future, to have a more precise understanding of the exact extent of crab PSC by vessels using trawl and pot gear in these areas, and to take appropriate action as necessary.

Based on the Council's recommendation, NMFS, in consultation with the Council, determined that the observer options are not necessary to achieve the Council's goal to improve Tanner crab PSC data, and they will not be part of the final action. Amendment 76 to the Fishery Management Plan for Groundfish of the GOA was approved on June 7, 2012 and a final rule to implement the restructured observer program was published in the federal Register on November 21, 2012 (77 FR70062).. This amendment provides for the restructure of the Observer Program that will improve overall catch data information for the GOA. Under the deployment plan, it is not possible to establish discrete areas with vessel specific observer requirements and maintain the random selection necessary to ensure statistically robust observations throughout the GOA. Because overall observer data will be improved, the restructured Observer Program will meet the Council's objective to have better information on Tanner crab PSC, not only in the areas described in the option, but also across the GOA. The comment period on the proposed rule closed (77 FR 23326, April 18, 2012), and the program is scheduled for implementation in 2013.

4.2 Groundfish and incidental catch species

Groundfish fishing occurs in the proposed closure areas primarily with trawl gear. Based on observer data, the majority of observed pot effort occurs to the northeast, rather than in the proposed closure areas.

Pelagic trawl vessels in the area target pollock. Color Figure 9, at the end of this document, illustrates observed pelagic trawl effort in reporting area 630. Nonpelagic trawl vessels target primarily flatfish, with some Pacific cod and pollock targeting as well. The distribution of observed catch is shown in Color Figure 2. Further information describing the groundfish fisheries affected by the proposed action can be found in Section 6.5, in the Regulatory Impact Review.

Effects of the Alternatives

Under Alternative 1, the status quo or no action alternative, all groundfish harvest during the GOA groundfish fisheries is counted toward the TAC for that species or species group. Groundfish stocks are assessed annually and are managed using conservative catch quotas. Incidental catch in the groundfish fisheries, as distinct from prohibited species (crab, halibut, herring, and salmon) catch, is also monitored. The Groundfish PSEIS (NMFS 2004) and the Harvest Specifications Environmental Impact Statement (NMFS 2007) both conclude that the groundfish species targeted and caught incidentally during the GOA groundfish fisheries are currently at sustainable population levels and are unlikely to be overfished under the current management program. Catch of prohibited species are not at levels that are likely to jeopardize the sustainability of the species. As a result, impacts on these species under the status quo alternative are not expected to be significant.

The alternatives, including the Preferred Alternative, are not expected to result in significant changes in groundfish or PSC levels. The proposed area closures may displace some vessels, and under Alternative 2, there may be some difficulty for vessels targeting shallow-water flatfish to fully harvest the TAC (see further discussion in Section 6.5.2). This is not anticipated under the Preferred Alternative, however. In general, the timing and general location of effort in the Central GOA groundfish fisheries is unlikely to change substantially as a result of the closures, although there may be an increased level of effort in localized areas, outside of the closures, as displaced vessels attempt to harvest their target fish elsewhere. However, effects on populations of the species caught in the GOA groundfish fisheries are not expected to be significant.

4.3 Marine mammals and seabirds

Marine mammals

Marine mammals occur in diverse habitats in the GOA, and include both resident and migratory species. Marine mammal species that occur in the GOA are in Table 28 (Allen and Angliss 2010 and NMFS 2007). The Groundfish PSEIS (NMFS 2004) provides descriptions of the range, habitat, and diet for these marine mammals. Annual stock assessment reports prepared by the National Marine Mammal Laboratory provide population estimates, population trends, and estimates of potential biological removals (Allen and Angliss 2010).

Direct and indirect interactions between marine mammals and the groundfish fisheries result from temporal and spatial overlap between commercial fishing activities and marine mammal occurrence. Direct interactions include injury or mortality due to entanglement in fishing gear, as well as disturbance. Indirect interactions include overlap in the size and species of groundfish important both to the fisheries and to marine mammals as prey. The GOA groundfish fisheries (pot, trawl, and hook-and-line) are classified as Category III fisheries under the Marine Mammal Protection Act (2009 draft List of Fisheries (74 FR 27739, June 11, 2009)). Category III fisheries are unlikely to cause mortality or serious injury to more than 1 percent of the marine mammal's potential biological removal level, calculated on an annual basis (50 CFR 229.2). Taking of marine mammals is monitored by the North Pacific observer program.

Marine mammals listed under the Endangered Species Act (ESA) that may be present in the GOA are listed in Table 28. All of these species are managed by NMFS, with the exception of Northern Sea Otter, which is managed by U.S. Fish and Wildlife Service. A Biological Opinion evaluating impacts of the groundfish fisheries on the endangered species managed by NMFS was completed in November 2000 (NMFS 2000). The western population segment of Steller sea lions was the only ESA-listed species identified as likely to be jeopardized or to have adverse modification of designated critical habitat from the Alaska groundfish fisheries. A detailed discussion of Steller sea lion population trends in the GOA is included in the most recent Biological Opinion (NMFS 2010), and is summarized here. Based on non-pup counts of Steller sea lions on trend sites throughout the range of the western DPS in the GOA and Aleutian Islands, the overall population trend for the western DPS of Steller sea lions is stable and may be increasing, but the trend is not statistically significant. The number of non-pups counted at trend sites increased by 12 percent between 2000 and 2008. However, counts increased by only 1 percent between 2004 and 2008 (DeMaster 2009).

Population trends differ across the range of the western DPS. Non-pup counts have declined in the Aleutian Islands, with the decline being most severe in the west and becoming less of a decline towards the east (7 percent decline in management area 543, 1 percent to 4 percent decline in management areas 542 and 541; NMFS 2010a). Pup and non-pup counts in the remainder of the western DPS range are either stable or increasing, ranging from 0 percent to 5 percent increases in population growth from 2000 to 2008 (NMFS 2010a).

Table 28 Marine Mammal Stocks Occurring in Gulf of Alaska

NMFS Managed Species		
	Species	Stocks
Pinnipedia	Steller sea lion*	Western U.S (west of 144E W long.) and Eastern U.S. (east of 144E W long.)
	Northern fur seal**	Eastern Pacific
	Harbor seal	Southeast Alaska, Gulf of Alaska, Bering Sea
	Ribbon seal	Alaska
	Northern elephant seal	California
Cetacea	Species	Stocks
	Beluga Whale*	Cook Inlet
	Killer whale	Eastern North Pacific Northern Resident, Eastern North Pacific Alaska Resident, Eastern North Pacific GOA, Aleutian Islands, and Bering Sea transient, AT1 transient**, West Coast Transient
	Pacific White-sided dolphin	North Pacific
	Harbor porpoise	Southeast Alaska, Gulf of Alaska, and Bering Sea
	Dall's porpoise	Alaska
	Sperm whale*	North Pacific
	Baird's beaked whale	Alaska
	Cuvier's beaked whale	Alaska
	Stejneger's beaked whale	Alaska
	Gray whale	Eastern North Pacific
	Humpback whale*	Western North Pacific, Central North Pacific
	Fin whale*	Northeast Pacific
	Minke whale	Alaska
	North Pacific right whale*	North Pacific
Blue whale*	North Pacific	
Sei whale*	North Pacific	
USFWS Managed Species

* ESA-listed species.

** Listed as depleted under the MMPA.

The Steller sea lion protection measures include area-specific closures around rookeries and haulouts and seasonal divisions of TACs, to disperse fishing effort throughout the year. The Pacific cod fishing season was divided into two periods: 60 percent of the TAC was allocated among the A season (Jan. 1 through June 10) and 40 percent to the B season (June 10 through Dec. 31). The objective was to limit the total amount of cod harvested in the first half of the year. Pacific cod is an important prey item of Steller sea lions (NMFS 2000).

Since 2000, the U.S. portion of the western population of Steller sea lions has been increasing. However, the 2004 count (38,988 animals) was still 7.4 percent lower than the 1996 count and 32.6 percent lower than the 1990 count. In the GOA, the 2004 count (9,005 animals) was 12.6 percent higher than the 2000 count (7,995 animals), but was 45.1 percent lower than the 1990 count. Although counts at some trend sites are missing for both 2006 and 2007, available data indicate that the size of the adult and juvenile portion of the western Steller sea lion population throughout much of its range (Cape St. Elias to Tanaga Island, 145°-178° W) in Alaska has remained largely unchanged between 2004 (23,107 animals) and 2007 (23,118 animals) (Fritz et al. 2007). However, there are significant regional differences in recent trends: increases between 2004 and 2007 in the eastern Aleutians and western/central Gulf of Alaska have largely been offset by decreases in parts of the central Aleutians and eastern Gulf of Alaska. The relative stability in the Cape St. Elias-Tanaga Island area coupled with the declining trends observed through 2006 west of Amchitka Pass suggest that the overall trend for the western stock in Alaska (through 2007) is either stable or declining slightly.

Incidental mortality of Steller sea lions during the GOA groundfish fisheries is summarized in Table 29. No incidental mortalities were observed in the fixed gear sectors. In the 2007 stock assessment, the GOA pollock trawl fishery contributes an estimated 0.5 percent of the total annual mortality to the western population of Steller sea lions attributed to commercial fisheries. The minimum estimate of incidental mortality due to commercial fishing activities in all waters off Alaska is 26.2 sea lions per year, which exceeds 10 percent of the potential biological removal (PBR), however the total estimated annual level of human-caused mortality and serious injury for all sources is below the PBR level (247) for this stock (Allen and Angliss 2010).

Table 29 Incidental mortality of Steller sea lions in the GOA groundfish fisheries (2002–2006) and estimate of the mean annual mortality rate, based on observer data

Fishery	Years	Observer coverage	Observed mortality	Estimated mortality	Mean annual mortality
GOA Pacific cod trawl	2002	23.2%	0	0	0
	2003	27.3%	0	0	
	2004	27.0%	0	0	
	2005	21.4%	0	0	
	2006	22.8%	0	0	
GOA pollock trawl	2002	26.0%	0	0	1.33 (CV = 0.66)
	2003	31.2%	1	2.1	
	2004	27.4%	0	0	
	2005	24.2%	1	4.2	
	2006	26.5%	0	0

Effects of the Alternatives on Marine Mammals

Impacts of the GOA groundfish fisheries on Steller sea lions were analyzed in the Programmatic SEIS (NMFS 2004), in the 2001 Environmental Impact Statements on the Steller sea lion protection measures (NMFS 2001), and in the 2010 Biological Opinion on the effects of the Alaska groundfish fisheries on ESA-listed species (NMFS 2010). Current management practices were found to have no adverse impacts on marine mammals, including Steller sea lions. As a result, the status quo alternative is not expected to have a significant impact on Steller sea lions or other marine mammals. NMFS has reinitiated consultation on the groundfish fisheries and their impact on listed species, including Steller sea lions. NMFS completed a biological opinion on the groundfish fisheries impacts on Steller sea lions in November 2010 (NMFS 2010). This opinion required no changes to the GOA Steller sea lion protection measures which remain in effect.

The alternatives, including the preferred alternative, would institute proposed area closures to protect *C. bairdi* crab around Kodiak Island, year round or seasonally, for some or all gear types. Some vessels may be exempted from the area closures if they meet specific conditions such as using approved gear modifications, or an observer coverage requirement. The proposed area closures may displace some vessels, and under Alternative 2, there may be some difficulty for vessels targeting shallow water flatfish to fully harvest the TAC (see further discussion in Section 6.5.2). This is not anticipated under the Preferred Alternative, however. In general, the timing and general location of effort in the groundfish fisheries is unlikely to change as a result of the closures, although there may be an increased level of effort in localized areas outside of the closures as displaced vessels attempt to harvest their target fish elsewhere. There would be no changes to the harvest specifications process or management of the fisheries relevant to Steller sea lion protection measures. Annual mortality of Steller sea lions is not expected to change under the proposed action, because fishing effort will remain similar to status quo. The alternatives are not likely to change fisheries activities in a way that would affect the potential for

competition for prey, disturbance, or incidental takes of marine mammals. Thus, this action would not likely have any effects on marine mammals beyond those already analyzed for the GOA groundfish fisheries in previous biological opinions and environmental impact statements (NMFS 2001, NMFS 2007).

Seabirds

Various species of seabirds occur in the GOA, including resident species, migratory species that nest in Alaska, and migratory species that occur in Alaska only outside of the breeding season. A list of species is provided below⁷. The Groundfish PSEIS (NMFS 2004) provides descriptions of the range, habitat, diet, abundance, and population status for these seabirds.

Species nesting in Alaska

Tubenoses-Albatrosses and relatives: Northern Fulmar, Fork-tailed Storm-petrel, Leach's Storm-petrel

Kittiwakes and terns: Black-legged Kittiwake, Red-legged Kittiwake, Arctic Tern, Aleutian Tern

Pelicans and cormorants: Double-crested Cormorant, Brandt's Cormorant, Pelagic Cormorant, Red-faced Cormorant

Jaegers and gulls: Pomarine Jaeger, Parasitic Jaeger, Bonaparte's Gull, Mew Gull, Herring Gull, Glaucous-winged Gull, Glaucous Gull, Sabine's Gull

Auks: Common Murre, Thick-billed Murre, Black Guillemot, Pigeon Guillemot, Marbled Murrelet, Kittlitz's Murrelet, Ancient Murrelet, Cassin's Auklet, Parakeet Auklet, Least Auklet, Wiskered Auklet, Crested Auklet, Rhinoceros Auklet, Tufted Puffin, Horned Puffin

Species that visit Alaska waters

Tubenoses: Short-tailed Albatross, Black-footed Albatross, Laysan Albatross, Sooty Shearwater, Short-tailed Shearwater

Gulls: Ross's Gull, Ivory Gull

Several species of conservation concern occur in the GOA as well (Table 30). Short-tailed albatrosses are listed as endangered under the ESA, while Kittlitz's Murrelet is a candidate species for listing under the ESA, and the U.S. Fish and Wildlife Service (FWS) is currently working on a 12-month finding for black-footed albatrosses.

Table 30 ESA-listed and candidate seabird species that occur in the GOA

Common Name	Scientific Name	ESA Status
Short-tailed Albatross	<i>Phoebastria albatrus</i>	Endangered
Steller's Eider	<i>Polysticta stelleri</i>	Threatened
Kittlitz's Murrelet	<i>Brachyramphus brevirostris</i>	Candidate
Black-footed Albatross	<i>Phoebastria nigripes</i>	FWS working on 12 month finding

FWS has primary responsibility for managing seabirds, and has evaluated effects of the BSAI and GOA FMPs and the harvest specifications process on currently listed species in two Biological Opinions (USFWS 2003a and 2003b). Both Biological Opinions concluded that the groundfish fisheries, including the GOA Pacific cod fishery, are unlikely to jeopardize populations of listed species or adversely modify or destroy critical habitat for listed species.

⁷ Source: (USFWS web site "Seabirds. Species in Alaska. Accessed at <http://alaska.fws.gov/mbmp/mbm/seabirds/species.htm> on August 31, 2007).

The groundfish fisheries have direct and indirect impacts on seabirds. Seabird take is the primary direct effect of fishing operations. Seabirds are taken in the hook-and-line fisheries in two ways. While hooks are being set, seabirds attracted to bait may become entangled in fishing lines. Seabirds are also caught directly on baited hooks. Seabirds are taken in the trawl fisheries when they are attracted by offal or discarded fish and become entangled in fishing gear. Indirect effects include impacts to food sources. The groundfish fisheries may reduce the biomass of prey species available to seabird populations. Fishing gear may disturb benthic habitat used by seabirds that forage on the seafloor and reduce available prey. Bottom trawl gear is the primary source of benthic habitat disturbance in the groundfish fisheries. Fishing activities may also create feeding opportunities for seabirds, for example when catcher processors discard offal.

Hook-and-line gear accounts for up to 85 percent of seabird takes in the BSAI and GOA groundfish fisheries combined, based on data averaged for 2007 to 2010 (NMFS 2011). In the GOA, these takes consisted of 52 percent fulmars, 18 percent albatrosses, 28 percent gull species, 1 percent unidentified seabirds, and 1 percent shearwater species (NMFS 2011). Most takes of Black-footed Albatross in waters off Alaska occurs in the GOA hook-and-line fisheries. From 2007 to 2010, an estimated 212 Black-footed Albatross were taken annually in the GOA hook-and-line fisheries. Total seabird takes in the GOA hook-and-line fisheries peaked in 2007 at 1,767 birds, and decreased to 156 birds in 2004. The incidental take rate in the GOA decreased from an annual average of 0.021 birds per 1,000 hooks from 1993 through 1999, to 0.01 birds per 1,000 hooks from 2000 through 2004.

Due to different sampling procedures on trawl vessels, two sets of estimates are calculated for seabird takes. Average annual take by trawl vessels in the GOA from 2007 through 2010 was 63 birds (NMFS 2011). Northern Fulmars comprised the entirety of takes by trawl vessels during this period. Seabird takes by the groundfish pot sector has historically been very low. Average annual loss in the GOA pot sector from 1993 through 2004 was 55 seabirds, less than 1 percent of the average annual seabird take in the groundfish fisheries (Fitzgerald et al. 2006). The total average annual take by pot vessels in the combined BSAI and GOA areas from 2007 through 2010 was 165 birds (NMFS 2011).

Effects of the Alternatives on seabirds

The Groundfish PSEIS (NMFS 2004) concluded that the current groundfish fisheries are not adversely impacting ESA-listed seabird species. Biological Opinions by the USFWS (2003a and 2003b) concluded that the groundfish fisheries, including the GOA Pacific cod fishery, are unlikely to jeopardize populations of listed species or adversely modify or destroy critical habitat for listed species. Based on current estimates of seabird takes, the status quo alternative is not expected to have a significant impact on seabird populations.

The alternatives, including the preferred alternative, would institute proposed area closures to protect *C. bairdi* crab around Kodiak Island, year round or seasonally, for some or all gear types. Some vessels may be exempted from the area closures, if they meet specific conditions such as using approved gear modifications, or an observer coverage requirement. The proposed area closures may displace some effort, and under Alternative 2, there may be some difficulty for vessels targeting shallow-water flatfish to fully harvest the TAC (see further discussion in Section 6.5.2). This is not anticipated under the Preferred Alternative, however. In general, the timing and general location of effort in the groundfish fisheries is unlikely to change as a result of the closures, although there may be an increased level of effort in localized areas outside of the closures, as displaced vessels attempt to harvest their target fish elsewhere. The hook-and-line sector would not be impacted by the proposed area closures. Thus, this action would not likely have any effects on seabird takes beyond those already analyzed for the GOA groundfish fisheries in previous biological opinions and environmental impact statements (USFWS 2003a,b; NMFS 2007).

4.4 Habitat

Benthic habitat is potentially impacted by fishing practices that contact the seafloor. The impacts of fishing gear on benthic habitat are discussed in the Groundfish PSEIS (NMFS 2004) and in Section 4.5. Essential fish habitat (EFH) is defined as those areas necessary to fish to spawn, breed, feed, and grow to maturity. Maps and descriptions of EFH for the GOA groundfish species are available in the EFH EIS (NMFS 2005). This document also describes the importance of benthic habitat to different groundfish species, and the impacts of different types of fishing gear on benthic habitat. In the hook-and-line fishery, anchors, groundline, ganglions, and hooks potentially contact the seafloor. The Pacific cod pot fishery has a very small footprint (an estimated 0.17 square mile footprint for the GOA and BSAI combined; NMFS 2005). In the trawl fishery, doors, sweeps, and bobbins on the net contact the seafloor.

Effects of the Alternatives

The effects of the GOA groundfish fisheries on benthic habitat and EFH were analyzed in the EFH EIS (NMFS 2005). Year-round area closures protect sensitive benthic habitat. Current fishing practices have minimal or temporary effects on benthic habitat and essential fish habitat. These effects are likely to continue under Alternative 1, and are not considered to be significant. The alternatives, including the Preferred Alternative, may displace some vessels, and under Alternative 2, vessels targeting shallow-water flatfish may have some difficulty fully harvesting the TAC (see further discussion in Section 6.5.2). In general, the timing and general location of effort in the groundfish fisheries is unlikely to change as a result of the closures, although there may be an increased level of effort in localized areas outside of the closures as displaced vessels attempt to harvest their target fish elsewhere. The alternatives provide additional protection to an area near Kodiak Island where area closures are proposed. The overall impacts on benthic and essential fish habitat under this alternative are not expected to be significant. However, some localized benefits within the proposed closure areas may result. Area closures to the use of nonpelagic trawl gear and gear modification on nonpelagic trawl gear used to target flatfish in the Central GOA combined form a suite of management measures recommended by the Council intended to reduce the potential adverse effects of nonpelagic trawl gear on benthic habitat.

4.5 Ecosystem

Ecosystems consist of communities of organisms interacting with their physical environment. Within marine ecosystems, competition, predation, and environmental disturbance cause natural variation in recruitment, survival, and growth of fish stocks. Human activities, including commercial fishing, also influence the structure and function of marine ecosystems. Fishing may change predator-prey relationships and community structure, introduce foreign species, affect trophic diversity, alter genetic diversity, and damage benthic habitats.

The GOA groundfish fisheries potentially impact the GOA ecosystem by relieving predation pressure on shared prey species (i.e., species which are prey for both groundfish and other species), reducing prey availability for groundfish predators, altering habitat, imposing PSC mortality, or by “ghost fishing” caused by lost fishing gear. Further information may be found in the Ecosystems Considerations Appendix to the Stock Assessment and Fisheries Evaluation report (NPFMC 2009a) and the Groundfish PSEIS (NMFS 2004).

Effects of the Alternatives

An evaluation of the effects of the GOA groundfish fisheries on the ecosystem is conducted annually in the Ecosystem Assessment section of the Stock Assessment and Fishery Evaluation report (NPFMC 2009a) and in the Harvest Specifications SAFE report (NPFMC 2009b). These analyses conclude that the current GOA groundfish fisheries do not produce population-level impacts to marine species or change

ecosystem-level attributes beyond the range of natural variation. Consequently, Alternative 1 is not expected to have a significant impact on the ecosystem.

Ecosystem effects of area closures to groundfish fishing

Ecosystem model simulations were conducted to evaluate the potential effects of reduced groundfish catch due to area closures for Tanner crab in the Central Gulf of Alaska (CGOA). Six scenarios of reduced groundfish fishing effort in the flatfish trawl, cod trawl, and pollock trawl fisheries were conducted to reflect potential outcomes of proposed crab closures. These simulations do not evaluate effects of possible displaced fishing effort outside of the proposed closure areas, but it is anticipated that PSC catch, if any, outside of the proposed closure areas would be minimal. These scenarios were compared with a base scenario of status quo (2009) effort. The results suggest that changes in flatfish trawl fishing effort would have the largest impacts in terms of changes in the biomass of both target and nontarget species. Isolated changes to the pollock trawl or cod trawl fisheries had little to no discernible ecosystem effects or impacts to Tanner crabs. The largest change in Tanner crab biomass due to the most extreme scenario (where effort in flatfish, pollock, and cod trawl fisheries were all reduced by the maximum expected amount simultaneously) was most likely to range from no change to a 9 percent reduction from the base scenario.

The ecosystem model used was derived from the full Gulf of Alaska food web model described in Aydin et al. (2007) by retaining biomass, diet, and fisheries catch data for regions only in the Central GOA (NMFS areas 620 and 630) and rebalancing. Changes to fisheries were modeled by converting the expected range of harvest declines for target species in target fisheries into reduced relative effort in those target fisheries. Changes in fishing gear effort better simulate the indirect effects of changes to fisheries (e.g. PSC reductions) as well as the indirect effects of leaving more predators and prey in the ecosystem. Seven fishing effort scenarios were implemented to simulate a range of outcomes from crab closures (reductions are relative to 2009 effort, all other fisheries held constant at 2009 level):

Scenario	Flatfish trawl effort	Cod trawl effort	Pollock trawl effort
Base	Constant 2009	Constant 2009	Constant 2009
ATF med	16.61% reduction	Constant 2009	Constant 2009
Cod med	Constant 2009	34.57% reduction	Constant 2009
Poll med	Constant 2009	Constant 2009	14.02% reduction
All med	16.61% reduction	34.57% reduction	14.02% reduction
All low	3.12% reduction	8.30% reduction	4.00% reduction
All high	33.23% reduction	69.15% reduction	28.03% reduction

Without incorporating uncertainty, these effort change scenarios resulted in the following 2010 catch changes (t) relative to the base scenario:

Scenario	Arrowtooth	Rock soles	Cod	Pollock	Tanner crabs
ATF med	-4,465	-1,225	-893	-251	-7
Cod med	-71	-6	-746	-27	-1
Poll med	-55	-22	-77	-1,667	0
All med	-4,591	-1,254	-1,719	-1,946	-8
All low	-869	-234	-368	-529	-1
All high	-9,195	-2,552	-3,450	-3,896	-15

After a 50 year simulation (allowing populations to adjust to changes) relative catch (t) was:

Scenario	Arrowtooth	Rock soles	Cod	Pollock	Tanner crabs
ATF med	-3,970	649	-626	-890	-19
Cod med	-88	6	542	-116	-6
Poll med	-131	20	119	-1,621	-1
All med	-4,181	672	0	-2,545	-25
All low	-787	140	49	-651	-5
All high	-8,558	1,103	-112	-4,942	-49

Note that with constant reduced effort, catches of rock sole and cod increase over the 50 year simulation in many or all scenarios because reduced effort allows the population to grow, so the model estimates more catch to be taken from this higher biomass even with reduced effort. Conversely, pollock catch declines further in some scenarios because predation mortality from their predators (cod and arrowtooth) increases more than their fishing effort decreases. The following plot shows the change in catch relative to the base scenario for these species in the All high scenario (prior to incorporating uncertainty):

Uncertainty was incorporated to assess changes in biomass due to reductions in fishing effort and the resulting ecosystem adjustments. The time series of relative effort for each scenario were used to force each of the 700 feasible ecosystems for 1990 through 2059, with experimental fishing in 2010 through 2059. The following plots show the ranges of relative biomass changes at the end of each run, averaged over the final 10 years (2050 through 2059). Species are arranged from those having the largest median change at left to those with the smallest median change at right for the top 30 species in each scenario. Note that different species are affected by each scenario. Blue bars show the 25 percent to 75 percent interquartile range of reduction or increase in a particular species relative to its original biomass. Error bars show the 5 percent to 95 percent interquartile range. The scenario name is in the upper right hand corner of each plot.

The three scenarios manipulating individual trawl fisheries show considerable contrast. The species most affected in each of these scenarios are PSC in each target fishery. Reduced catch in the cod trawl and pollock trawl fisheries alone had very small impacts to any species in the ecosystem, even in the 5 percent to 95 percent interquartile range for the target species. In these scenarios, Tanner crabs (labeled “Bairdi” in plots) were not included in the top 30 species for Poll med, and were predicted to remain close to base biomass for Cod med (extreme low predicted biomass at the 5 percent interquartile was 2 percent below base).

Reduced catch in only the flatfish trawl fishery was predicted to have larger impacts, increasing biomass for thornyhead rockfish, Dover sole, longnose skate, shortraker rockfish even at the 5 percent quantile. Rock soles were also predicted to increase although there is more uncertainty in how much (in some models they increased more than threefold). Tanner crab rank 27th in the top 30 biggest median biomass changes in this scenario. The 25 percent to 75 percent prediction for Tanner crab biomass was to decline between 3.5 and <1 percent relative to base; models at the 5 percent to 95 percent extreme ranges predicted between a 13.7 percent decline and a 3.4 percent increase in biomass.

When fishery changes were implemented across all three trawl fisheries simultaneously, the largest predicted changes were to species that also changed when only the flatfish trawl fishery effort decreased. The All med scenario combines the same changes implemented separately in ATF med, Cod med, and Poll med. The top 9 species changed in All med were identical to those in ATF med, as were the top 9 species in All high. However, the combined effects of changes to all fisheries were also apparent in these scenarios, with species such as sleeper sharks (PSC in pollock trawl) and cod (target of cod and PSC in other trawl fisheries) showing larger changes than in the ATF med scenario. The difference between catch levels between the All low, All med, and All high scenarios appeared to simply scale up (or down) the effects to particular species, with the All high scenario having the largest overall effects.

Tanner crab ranked 23rd in the top 30 biggest median biomass changes in the All low, All med, and All high scenarios. The predicted interquartile ranges of Tanner crab biomass change in each model were:

Scenario	Rank	5%	25%	Median	75%	95%
ATF med	27 th	-13.7%	-3.5%	-1.4%	-0.2%	3.4%
Cod med	10 th	-2.1%	-0.5%	-0.1%	0.0%	0.3%
Poll med	55 th	-0.5%	-0.1%	0.0%	0.1%	0.4%
All med	23 rd	-16.0%	-4.2%	-1.7%	-0.3%	3.4%
All low	23 rd	-2.6%	-0.8%	-0.3%	-0.1%	0.4%
All high	23 rd	-38.8%	-9.0%	-3.5%	-0.6%	18.5%

Modeling fishery changes separately suggested that major changes due to the combined fishery effort reductions were primarily due to changes in the flatfish trawl fishery. In this model, the flatfish trawl fishery is generalized and does not distinguish between deep-water and shallow-water flatfish targets; its primary catch is arrowtooth flounder. In all scenarios, the expected change to Tanner crab biomass ranked fairly low among species and was expected to be small (< 10 percent reductions in the more likely 25 percent to 75 percent interquartile ranges) relative to the base scenario with constant effort in all fisheries. All high, the most extreme scenario with the largest simultaneous changes to trawl fisheries had the largest potential negative effect on Tanner crabs. However, the 5 percent to 95 percent interquartile range for the All high scenario shows considerable uncertainty, with outcomes ranging from a 39 percent decline in crab biomass to a 19 percent increase. If the changes to fisheries resulting from the proposed trawl closure areas are of the magnitude implemented in the All high scenario, then indirect impacts to Tanner crabs should be weighed against the potential benefits of protecting them in critical habitat. However, if changes to fisheries are expected to be lower than that extreme scenario, changes to Tanner

crab biomass resulting from indirect impacts may be small and difficult to distinguish from observation error in abundance estimates.

Alternatives 2, 3, and the Preferred Alternative will result in the same overall level of groundfish harvest as Alternative 1. As a result, the alternatives are not expected to have a significant impact on the ecosystem.

4.6 Cumulative effects

Analysis of the potential cumulative effects of a proposed action and its alternatives is a requirement of NEPA. Cumulative effects result from the incremental impact of the proposed action in addition to past, present, and reasonably foreseeable future actions (RFFAs). The Alaska Groundfish Fisheries PSEIS (NMFS 2004) assesses the potential direct and indirect effects of groundfish FMP policy alternatives in combination with other factors that affect physical, biological, and socioeconomic components of the BSAI and GOA environment. The most recent analysis of RFFAs for the groundfish fisheries is in the Harvest Specifications EIS (NMFS 2007). No additional RFFAs have been identified for this proposed action. The RFFAs are described in the Harvest Specifications EIS Section 3.3 (NMFS 2007), are applicable for this analysis, and are incorporated by reference. A summary table of these RFFAs is provided below. The table summarizes the RFFAs identified applicable to this analysis that are likely to have an impact on a resource component within the action area and timeframe. Actions are understood to be human actions (e.g., a proposed rule to designate northern right whale critical habitat in the Pacific Ocean), as distinguished from natural events (e.g., an ecological regime shift). CEQ regulations require a consideration of actions, whether taken by a government or by private persons, which are reasonably foreseeable. This is interpreted as indicating actions that are more than merely possible or speculative. Actions have been considered reasonably foreseeable if some concrete step has been taken toward implementation, such as a Council recommendation or the publication of a proposed rule. Actions simply under consideration have not generally been included because they may change substantially or may not be adopted, and so cannot be reasonably described, predicted, or foreseen. Identification of actions likely to impact a resource component within this action's area and time frame will allow the public and Council to make a reasoned choice among alternatives.

This analysis provides a brief review of the RFFA that may affect environmental quality and result in cumulative effects. Future effects include harvest of federally managed fish species, impacts on prohibited and forage fish species, marine mammals and seabirds, current habitat protection from federal fishery management measures, efforts to protect endangered species by other federal agencies, and other non-fishing activities and natural events. The actions under consideration would have no significant impacts on public health or safety.

There is no new information available that suggests the effects of climate change combined with the effects of this action will have effects beyond those already discussed in the Final Alaska Groundfish Fisheries PSEIS (NMFS 2004, and the Harvest Specifications EIS (NMFS 2007).

The Council, NMFS, and the State of Alaska have taken actions that indicate a willingness to adapt fishery management to be proactive in the face of changing climatic conditions, both natural and anthropomorphic. The Council currently receives an annual update on the status and trends of indicators of climate change in the GOA through the presentation of the "Ecosystem Considerations" chapter of crab and groundfish SAFE reports. It is likely that as other impacts of climate change become apparent, fishery management will also adapt in response. Because of the large uncertainties as to what these impacts might be and our current inability to predict such change, it is not possible to estimate what form these adaptation may take. Any changes to fisheries management in response to potential effects of

climate change would be subject to analysis under NEPA, incorporating the latest information available on climate indicators that are tracked for the harvest specifications process in the SAFE report.

Reasonably Foreseeable Future Actions

Ecosystem-sensitive management	<ul style="list-style-type: none"> Increasing understanding of the interactions between ecosystem components, and ongoing efforts to bring these understandings to bear in stock assessments, Increasing protection of ESA-listed and other non-target species components of the ecosystem, Increasing integration of ecosystems considerations into fisheries decision-making
Fishery rationalization	<ul style="list-style-type: none"> Continuing rationalization of federal fisheries off Alaska, Fewer, more profitable, fishing operations, Better harvest, PSC, and bycatch control, Rationalization of groundfish in waters in and off Alaska, Expansion of community participation in rationalization programs
Traditional management tools	<ul style="list-style-type: none"> Authorization of groundfish fisheries in future years, Increasing enforcement responsibilities, Technical and program changes that will improve enforcement and management
Other federal, state, and international agencies	<ul style="list-style-type: none"> Future exploration and development of offshore mineral resources Reductions in United States Coast Guard fisheries enforcement activities Continuing oversight of seabirds and some marine mammal species by the USFWS Expansion and construction of boat harbors Expansion of state groundfish fisheries Other state actions Ongoing EPA monitoring of seafood processor effluent discharges
Private actions	<ul style="list-style-type: none"> Commercial fishing Increasing levels of economic activity in coastal zone off Alaska Expansion of aquaculture

Beyond the cumulative impacts analysis document in the Groundfish PSEIS, no additional past, present, or RFFAs have been identified that would result in cumulative impacts on the natural and physical environment (including fish stocks, essential fish habitat, ESA-listed species, marine mammals, seabirds, or marine ecosystems), fishing communities, fishing safety, or consumers when considered with the preferred alternative. The preferred alternative, in combination with other actions, may have additional economic effects on sectors participating in the Central GOA flatfish fisheries. In recent years, several regulatory changes implemented to protect Steller sea lions have had economic effects on participants in the GOA groundfish fisheries. Several recent or reasonably foreseeable future actions are expected to have additional social and economic effects on participants in the GOA groundfish fisheries. These actions include GOA and BSAI trawl LLP recency, GOA Pacific cod sector allocations, GOA halibut PSC limits, and GOA *C. bairdi* area closures. Economic impacts of this proposed action are discussed further in Section 6.

5 Management and Enforcement Considerations

Alternative 2 provides a series of options to close certain areas around Kodiak to directed fishing for groundfish by vessels using specific gear types. Some options would allow directed fishing for groundfish in these areas by vessels using specific gear types or specified types of modified gear. Alternative 3 would allow fishing in these areas, but increase observer coverage requirements for selected vessels using trawl or pot gear. The Preferred Alternative is a combination of Alternatives 2 and 3.

Closures by NMFS for vessels directed fishing for groundfish in these areas would apply only to Federal waters. These closures would not apply in State of Alaska waters, so would not affect the adjacent parallel or State waters fisheries. Directed fishing for groundfish is defined as fishing by a vessel with a Federal Fisheries Permit (FFP) that results in retaining more than the maximum retainable amounts (MRAs) of any groundfish managed by NMFS under the GOA groundfish FMP. MRAs for groundfish in the GOA fisheries are enumerated in Table 10 to part 679. All operators of vessels named on an FFP must comply with NMFS recordkeeping and reporting requirements and observer coverage requirements in the Federal fisheries. In addition, vessel operators who hold an FFP must comply with vessel monitoring system (VMS) requirements if they use nonpelagic trawl gear or dredge gear in the GOA, or if they participate in a directed fishery for Atka mackerel, Pacific cod, or pollock, or in the Central GOA Rockfish Program.

5.1 Alternatives 2 and 3: Area closures

The four closure areas being considered under Alternatives 2 and 3 have high Tanner crab abundance, based on crab surveys conducted annually by the Alaska Department of Fish and Game (ADF&G). In these areas, vessels using nonpelagic (bottom) trawl gear predominantly target Pacific cod, arrowtooth flounder, and shallow-water flatfish. Vessels using pot gear predominantly target Pacific cod. Vessels using pelagic trawl gear target both pollock and rockfish in these areas.

The boundaries of the proposed closure areas are defined by existing ADF&G statistical areas and by polygons defined by latitude and longitude coordinates. Closure areas defined in this manner are easier for both the regulated industry to understand and comply with, as well as enforcement entities to patrol and enforce. The proposed closure areas present no noteworthy enforcement challenges. The proposed closure areas would be principally enforced by using information from VMS units aboard vessels required to carry VMS. Most of the vessels subject to the proposed closure areas are already required to carry VMS units due to their participation in existing fisheries subject to VMS requirements.

The proposed areas are located relatively close to the Port of Kodiak, and would be expected to receive a relatively high amount of aerial and surface patrol by USCG platforms, as these patrols depart and arrive into the Kodiak USCG base. These proposed closure areas are also located in areas of high transit activity by the Kodiak and GOA-based fishing fleets and other maritime vessels. For this reason, one could expect a higher likelihood of reporting potential violations by the fishing and maritime community.

5.2 Alternative 2, Component 2, Options 1 and 2

Both year round and seasonal closures are being considered. Aside from personnel to perform the monitoring activities, enforcement of year round versus seasonal closures presents no additional monitoring challenges.

5.3 Alternative 2, Suboption 3: Gear modification exemption

Proposed modified gear requirements under Suboption 3, such as trawl sweep modifications or pot escapement mechanisms, require a detailed description in regulations of the specific gear modification that would be required to qualify for exemption of the area closures. In April 2012, the Council recommended vessels using nonpelagic trawl gear to target flatfish in the Central GOA use approved modified gear to reduce the potential adverse effects of nonpelagic trawl gear on benthic habitat and to reduce unobserved Tanner crab injury and mortality. In the GOA, fishing for flatfish includes vessels targeting shallow-water flatfish, deep-water flatfish, arrowtooth flounder, rex sole, and flathead sole. These species and species groups are defined in the annual groundfish harvest specification proposed and final rules each year. Area closures to the use of nonpelagic trawl gear and gear modification on nonpelagic trawl gear used to target flatfish in the Central GOA combined form a suite of management measures recommended by the Council intended to reduce injury and mortality, both observed and unobserved, of Tanner crab and to reduce the potential adverse effects of nonpelagic trawl gear on benthic habitat.

Nonpelagic trawl gear modifications would be enforced in the same manner as the existing requirements for tunnel eyes on pot gear and trawl sweeps in the flatfish fisheries of the Bering Sea. During boardings at sea, both the USCG and OLE check vessels to ensure proper use and functionality of any gear modifications. Most vessels subject to the proposed alternatives are currently required to operate VMS. Thus, if OLE or USCG desired to check gear compliance of vessels fishing in the closure areas, these vessels could readily be identified.

5.4 Alternative 2, Suboptions 4 and 5: Pelagic trawl gear exemption

Suboptions 4 or 5 would exempt vessels using pelagic trawl gear from the proposed area closures. The principal fisheries prosecuted by vessels using pelagic trawl gear in these areas are pollock and rockfish. Vessels used to conduct these fisheries are all required to operate VMS.

As described in Section 3.1.2 and Figure 3, there are several areas around Kodiak Island that already are closed to nonpelagic (bottom) trawling. These closure areas overlap with some of the closure areas proposed under Alternative 2. Regulations governing these closures are in 50 CFR part 679 (§ 679.22(b)). These regulations state that “no person may trawl” in these areas “from a vessel having any trawl other than a pelagic trawl either attached or on board”. Compliance with this requirement is based on examining the gear on board the vessel and determining if it meets the requirements of pelagic trawl gear defined in § 679.2. These regulations contain a list of ten items that define pelagic trawl gear (see definition of “authorized gear”). However, a net meeting the physical description of a pelagic trawl is capable of being fished in contact with the sea floor.

If directed fishing for pollock using bottom trawl gear is closed, NMFS also applies a “trawl gear performance standard” (50 CFR 679.7(a)(14)). Under this standard, it is unlawful to possess aboard a vessel, at any point in time, 20 or more crab of any species, with a carapace width of more than 1.5 inches. Enforcement of this standard on any vessel (observed or unobserved) is difficult, and it is virtually impossible to monitor and enforce on unobserved vessels. Anecdotal reports from operators and observers indicate this trawl gear performance standard is not difficult to overcome by slowly dumping the catch, sorting, and discarding crab from the catch. The existing tools are not considered adequate to provide effective enforcement of a prohibition for directed fishing using nonpelagic trawl gear in the proposed closure areas. However, if the vessels are simply prohibited from having nonpelagic trawl gear aboard while in the proposed closure areas, OLE could board vessels to check for the presence of nonpelagic

trawl gear. If the concern is pelagic gear contacting the sea floor, the only tool OLE currently has is the use of the effectively unenforceable “trawl gear performance standard” described above.

NMFS recommends that the regulations described above be used as a basis for any additional closures to nonpelagic trawling under this action. The prohibition against having nonpelagic trawl gear onboard the vessel when trawl fishing is occurring would apply in general, and the “trawl gear performance standard” also would apply for vessels directed fishing for pollock. Transiting closed areas with nonpelagic trawl gear aboard would be allowed.

5.5 Alternative 3: Exemption to area closures with increased observer coverage

Alternative 3 would allow fishing in the proposed closure areas by vessels using trawl gear only if they carry an observer 100 percent of the days they conducted directed fishing for groundfish in these areas. All vessels using pot gear to directed fish for groundfish in these areas would be required to have 30 percent observer coverage. In addition, observer coverage inside these closure areas would be separate from, and would not count toward, meeting a vessel’s 30 percent observer coverage requirements for fishing outside of these closure areas.

The following observer coverage requirements apply to vessels that may be fishing in these proposed closure areas:

- Amendment 80 vessels, except for the F/V *Golden Fleece*, are required to have at least one observer (100 percent coverage) while harvesting or processing groundfish in the GOA.
- Catcher/processors in a CGOA rockfish cooperative or fishing in the rockfish limited access fishery are required to have at least two observers (200 percent coverage) while fishing under the Rockfish Program. Catcher/processors subject to sideboard limits under the Rockfish Program (except those in the opt-out fishery) also are required to have at least two observers while fishing under the Rockfish Program. Catcher/processors assigned to the opt-out fishery and subject to a sideboard limit under the Rockfish Program area required to have at least one observer (100 percent coverage) during certain times of the year, in certain areas of the GOA.
- Catcher vessels in the Rockfish Program limited access fishery are required to have one observer while fishing under the Rockfish Program. Catcher vessels subject to sideboard limits under the Rockfish Program are required to have one observer during certain times of the year, and in certain areas of the GOA.

For all other vessels and fisheries, the standard observer coverage at §679.50(c)(1) applies.

- For vessels using gear other than pot gear:
 - Vessels 125 feet length overall (LOA) or greater are required to carry an observer 100 percent of all fishing days while fishing for groundfish.
 - Vessels between 60 feet and 124 feet that participate for more than 3 fishing days in any directed fishery for groundfish in a calendar quarter are required to carry an observer 30 percent of fishing days by quarter, and at least one fishing trip per quarter and fishery category.
- Vessels equal to or greater than 60 feet LOA using pot gear that participate for more than 3 fishing days in any directed fishery for groundfish in a quarter are required to carry an observer for at least 30 percent of the total number of pot retrievals for that quarter, and for at least one

entire fishing trip using pot gear in a quarter in each fishery category in which the vessel participates.

- Vessels less than 60 feet LOA are not required to carry observers.

100 percent observer coverage requirements for vessels using trawl gear: Enforcing 100 percent observer coverage on vessels using trawl gear fishing in the closure areas does not present any unreasonable monitoring and enforcement challenges, as long as enforcement entities can identify which vessels are directed fishing for groundfish in the closure areas. Once a vessel is identified as directed fishing for groundfish in the area, the OLE can monitor compliance with the observer coverage requirement by comparing vessel activity with information about where and when observers were deployed on vessels.

Under Alternative 3, any vessel using trawl gear currently in the 30 percent observer coverage category that would be required to carry 100 percent observer coverage inside the closure areas would not be allowed to count the fishing days inside these areas towards meeting the 30 percent observer coverage requirements for fisheries outside these areas. This provision was added to the alternative to address the concern NMFS identified in the initial review draft that increased observer coverage requirements inside the proposed closure areas could decrease the observer data available from fishing outside of the closure areas. While this provision addresses that concern, the other concern identified in the initial review draft persists, because it is a feature of the current process for obtaining observer coverage for vessels subject to 30 percent coverage requirements.

NMFS uses observer data and extrapolates PSC on observed trips to similar unobserved trips in the larger Federal reporting area (by processing sector, week ending date, target fishery, gear, and Federal reporting area). NMFS does not create separate PSC estimates for each ADF&G state statistical area or for catcher vessels fishing inside and outside of closure areas, such as those proposed in this action. It is not known whether data collected from the proposed closure areas would be representative of fishing over the entire reporting area. However, through ongoing work, NMFS is working to improve the estimation process in concert with the observer restructuring efforts. The restructured program would enable NMFS to define estimation strata and randomly select trips at a consistent rate within them. Action to increase observer coverage in this one GOA area without modifications to the NMFS catch estimation process could result in estimates which are biased by data from this specific area. Thus, NMFS would need to make changes to the current estimation process to accommodate this change in coverage. Likely NMFS would need to handle estimation for this specific area discrete from other areas in the GOA. Modifications to the catch estimation process would be complex and expensive, and would compete with other priorities for additions and improvements to NMFS's catch accounting system.

30 percent coverage for vessels using pot gear: Alternative 3 would require a vessel *of any size* using pot gear that participated for more than 3 fishing days in any directed fishery for groundfish in a calendar quarter to carry an observer for at least 30 percent of the total number of pot retrievals that occurred inside the closure areas each quarter. In addition, vessels equal to or greater than 60 feet would not be allowed to use the observed pot retrievals that occurred inside the closure area to comply with their 30 percent observer coverage requirements for fishing that occurred outside the closure areas. Vessels using pot gear to fish for groundfish currently are participating primarily in directed fisheries for Pacific cod.

30 percent coverage requirement related to at least one fishing trip per quarter per fishery category: NMFS recommends that, if Alternative 3 is selected as the preferred alternative, the current 30 percent observer coverage requirement for coverage of at least one fishing trip in a quarter for each fishery category would continue to apply to all fishing during a quarter and would not be applied separately inside and outside the closure areas. For vessels using pot gear, this distinction is not as relevant, because they are participating primarily in directed fisheries for Pacific cod. Therefore, the requirement for separate accounting of pot retrievals inside and outside the closure areas will effectively require observer

coverage on at least one Pacific cod fishing trip each quarter inside the closure areas and at least one Pacific cod fishing trip outside the closure areas.

Vessels less than 60 feet LOA: Some vessels less than 60 feet LOA may have fished in the proposed closure areas in the past. Under Alternative 3, any vessels of this size class would be required to carry observers for at least some of the fishing inside the proposed closure areas (unless they didn't meet the minimum threshold for observer coverage of 3 days per quarter). Although some vessel operators may choose to fish outside the closure areas rather than incur the cost of the required observer coverage, some of these vessels may seek observer coverage. They would be required to comply with existing safety and all other vessel requirements in 50 CFR part 679.50.

Interaction with the Observer Restructuring Action

Proposed Alternative 3 would interact with the Observer Restructuring action recently approved by the Secretary of Commerce and implemented in 2013. In the restructured groundfish Observer Program, the designation of 100 percent observer coverage determines the fee structure and service delivery model to which an operation is subject. Vessels and processors will be classified in regulation into two observer coverage categories: <100 percent or \geq 100 percent. Generally, all catcher/processors, motherships, catcher vessels fishing under cooperatives with transferable quotas, and shoreside processors taking deliveries of AFA and CDQ pollock would be in the \geq 100 percent category. An exception to this category is the halibut and sablefish IFQ fisheries, which will be less than fully observed (<100 percent coverage category) under the observer restructuring action. All other catcher vessels and most shoreside processors will also be in the <100 percent coverage category.

Current regulations include increased observer coverage requirements for two "special areas," similar to those proposed under Alternative 3:

- Nearshore Bristol Bay Trawl Closure area: Under § 679.50(c)(1)(ix), any catcher/processor or catcher vessel using trawl gear to fish for groundfish in the Nearshore Bristol Bay Trawl Closure area must carry an observer during 100 percent of its fishing days in this area.
- Red King Crab Savings Area: Under § 679.50(c)(1)(viii), any catcher/processor or catcher vessel using pelagic trawl gear, pot, jig, or longline gear to fish for groundfish in the Red King Crab Savings Area (RKCSA) of the Bering Sea must carry an observer during 100 percent of its fishing days in this area. In addition, any catcher/processor or catcher vessel used to fish for groundfish in the Red King Crab Savings Subarea when this subarea is open to fishing for groundfish with nonpelagic trawl gear must carry an observer during 100 percent of its fishing days in which the vessel uses nonpelagic trawl gear in the subarea.

If the Council recommended increased observer coverage for vessels fishing within the GOA Tanner crab protection areas under Alternative 3, this would add a third special area with 100 percent observer coverage requirements to NMFS's current regulations. These specific requirements for 100 percent observer coverage within special areas currently are not included in the categories that would require \geq 100 percent observer coverage under the observer restructuring alternatives. Therefore, unless otherwise specified by the Council, increased observer coverage requirements under Alternative 3, and the 100 percent coverage requirements for the two special areas in the BSAI, would be removed from NMFS regulations if the vessels in the <100 percent observer coverage category in the relevant management area were subject to assignment of observer coverage under a sampling plan as described in the observer restructuring analysis.

Based on the Council's recommendation for either increased observer coverage requirements under this action or addressing improved PSC catch monitoring under the restructured observer program, NMFS, in

consultation with the Council, decided not to pursue the increased observer coverage requirements described herein as the restructured observer program was implemented in 2013 (77 FR 70062, November 21, 2012), the restructured observer program is anticipated to meet the Council's desire more accurate and reliable information on fishing activities. Details of the restructured observer program are available in the proposed rule (77 FR 23326, April 18, 2012). The restructured observer program would improve the quality of fisheries data, including the catch information for Tanner crab in the groundfish fisheries. Vessels under the restructured observer program would be either fully or partially observed. A randomized system for the assignment of observer coverage throughout the GOA for partially observed vessels would be used to reduce potential bias in the observer data. Selecting locations for increased observer coverage would reduce the ability to randomize observer assignments and therefore potentially bias observer data. This would not meet the Council's intent to improve the quality of observer information under Amendment 76. For these reasons, increased observer coverage in specific areas under Amendment 89 will not be pursued. It was the intent of the Council to recommend increased observer coverage in the event the amendments restructuring the observer program were disapproved or if implementation of the restructured observer program was delayed.

Many vessels operating in the Bering Sea and Aleutian Islands management area are already included in a sector that requires ≥ 100 percent observer coverage in the observer restructuring analysis, and this coverage requirement would continue to apply when they fished inside the Nearshore Bristol Bay Trawl Closure area or the RKCSA. Therefore, the impact of removing the 100 percent coverage requirements for the BSAI special areas under observer restructuring may not have a big impact on the actual level of observer coverage that occurs in these areas. However, many of the vessels currently operating in the GOA are not included in the ≥ 100 percent observer coverage category under the restructuring alternatives. If increased observer coverage implemented under Alternative 3 was removed under observer restructuring, any vessel that did not fall into the ≥ 100 percent observer coverage category may or may not end up carrying an observer when fishing in the areas considered under the GOA Tanner crab area closures action.

However, the observer restructuring program does accommodate continuation of 100 percent observer coverage requirements for all vessels within these special areas. Vessels that are in the < 100 percent coverage category would pay an exvessel value-based fee for observers, and these vessels would be subject to an annual sampling plan developed by NMFS. Should vessels choose to fish in the special areas, the sample design could require that they carry observers 100 percent of the time they are directed fishing for groundfish in these areas. Thus, even though many of the affected vessels would not have 100 percent coverage any other time or in any other area, the observer restructuring action allows for flexibility in determining coverage on vessels in the < 100 percent coverage category. If a group of vessels is determined to need 100 percent coverage at specific times of the year, seasons, or areas, NMFS could direct observer deployment to accommodate those needs. The fee paid by those vessels would not change, but the coverage amount could be modified to account for those circumstances; this flexibility is part of the impetus of restructuring. This accommodation in the sampling plan is not currently described in the observer restructuring analysis, as that level of detail by sector was not deemed necessary. Establishing special areas of 100 percent observer coverage would significantly complicate the current sampling plan and necessarily reduce the amount of coverage days available for other fisheries and management priorities in the GOA. The vessel selection plan currently included in the observer restructuring analysis does not assign observer coverage based on what a vessels intends to do. Instead, it takes parameters such as vessel length and gear type, which are known in advance, and assigns random coverage of trips based on a pre-determined coverage rate. Vessels would call in prior to trips and be selected for coverage or not regardless of where they planned to fish.

6 Regulatory Impact Review and Probable Economic and Socioeconomic Impacts

6.1 Introduction

This Regulatory Impact Review (RIR) evaluates the costs and benefits of four alternatives that evaluate proposed area closures to protect *C. bairdi* Tanner crab around Kodiak Island. Included in the alternatives are options to apply the closures year round or seasonally, and to pot and/or trawl gear types. Additionally, some vessels may be exempted from the area closures if they meet specific conditions such as using approved gear modifications or an observer coverage requirement.

6.2 What is a Regulatory Impact Review

This RIR is required under Presidential Executive Order 12866 (58 FR 51735, September 30, 1993). The requirements for all regulatory actions specified in EO 12866 are summarized in the following statement from the order:

In deciding whether and how to regulate, agencies should assess all costs and benefits of available regulatory alternatives, including the alternative of not regulating. Costs and benefits shall be understood to include both quantifiable measures (to the fullest extent that these can be usefully estimated) and qualitative measures of costs and benefits that are difficult to quantify, but nonetheless essential to consider. Further, in choosing among alternative regulatory approaches agencies should select those approaches that maximize net benefits (including potential economic, environmental, public health and safety, and other advantages; distributive impacts; and equity), unless a statute requires another regulatory approach.

EO 12866 further requires that the Office of Management and Budget review proposed regulatory programs that are considered to be “significant.” A significant regulatory action is one that is likely to—

- Have an annual effect on the economy of \$100 million or more or adversely affect in a material way the economy, a sector of the economy, productivity, competition, jobs, local or tribal governments or communities;
- Create a serious inconsistency or otherwise interfere with an action taken or planned by another agency;
- Materially alter the budgetary impact of entitlements, grants, user fees, or loan programs or the rights and obligations of recipients thereof; or
- Raise novel legal or policy issues arising out of legal mandates, the President’s priorities, or the principles set forth in this Executive Order.

6.3 Problem Statement

The Council formulated a problem statement in October 2009, to initiate this analysis, and revised it in April and October 2010:

Tanner crab are a prohibited species in the Gulf of Alaska (GOA) groundfish fisheries. Directed fisheries for Tanner crab in the GOA are fully allocated under the current

limited entry system. No specific conservation measures exist in the GOA to address adverse interactions with Tanner crab by trawl and fixed gear sectors targeting groundfish and low observer coverage in GOA groundfish fisheries limits confidence in the assessment of Tanner crab PSC in those fisheries, and a greater level of observer coverage in the appropriate areas may provide the Council with a higher level of confidence in the assessment of any PSC occurring in the designated areas as a basis for future management actions as necessary. Trawl sweep modifications have been effective in reducing unobserved PSC mortality of Tanner crab in the Bering Sea, and similar effects may be realized in the Gulf of Alaska if modified trawl sweeps are employed in those groundfish fisheries.

6.4 Description of the Alternatives

The alternatives evaluated in this analysis were adopted by the Council in October 2009, and modified during initial review in April 2010.

Alternative 1: Status Quo – No action

Alternative 2: Close the areas specified below to pot and trawl groundfish fisheries.

Component 1: Area definition

ADF&G Northeast Section

Option 1: Statistical Area 525807 and the area east of Statistical Area 525807 north of 58 degrees latitude, south of 58 degrees 15 min. latitude and west of 151 degrees 30 min. longitude.

Option 2: Chiniak Gully (Four corners at 152°19'34" W x 57°49'24" N by 57°29' N x 151°20' W by 57°20' N x 151°20' W by 57° x 152°9'20' W), excluding State waters

6.4.1 Council's preferred alternative

In October 2010, the Council adopted the following recommendations as its preferred alternative for this action. The recommendations combine elements of both Alternatives 2 and 3.

Close the area specified below to trawl groundfish fisheries, and require observer coverage for the pot groundfish fishery.

Area definition:

ADF&G Northeast Section: Statistical Area 525807 and the area east of Statistical Area 525807 north of 58 degrees latitude, south of 58 degrees 15 min. latitude and west of the longitude line extending north from the eastern boundary of the Type 1 red king crab closure area (Figure 4).

Closure timing: Year round

Vessels using pelagic trawl gear to directed fish for pollock would be exempt from the closures

Observer coverage for pot groundfish fishery

In order to fish in the area, require 30 percent observer coverage on all pot groundfish vessels less than 125 feet. Note, fishing days and observer coverage in these areas would be separate from, and would not count towards meeting a vessel's overall 30 percent groundfish observer coverage requirement. The Council encourages the agency to incorporate, to the extent possible, in the new fee-based observer program, an observer deployment strategy that ensures adequate coverage to establish statistically robust observations in the area described.

Require observer coverage for the nonpelagic trawl and pot groundfish fisheries in the areas specified below

In order to fish in the areas specified below, require 100 percent observer coverage on all nonpelagic trawl groundfish vessels and 30 percent observer coverage on all pot groundfish vessels less than 125 feet. Note, fishing days and observer coverage in these areas would be separate from, and would not count towards, meeting a vessel's overall 30 percent groundfish observer coverage requirement. The Council encourages the agency to incorporate, to the extent possible, in the new fee-based observer program, an observer deployment strategy that ensures adequate coverage to establish statistically robust observations in the areas described below.

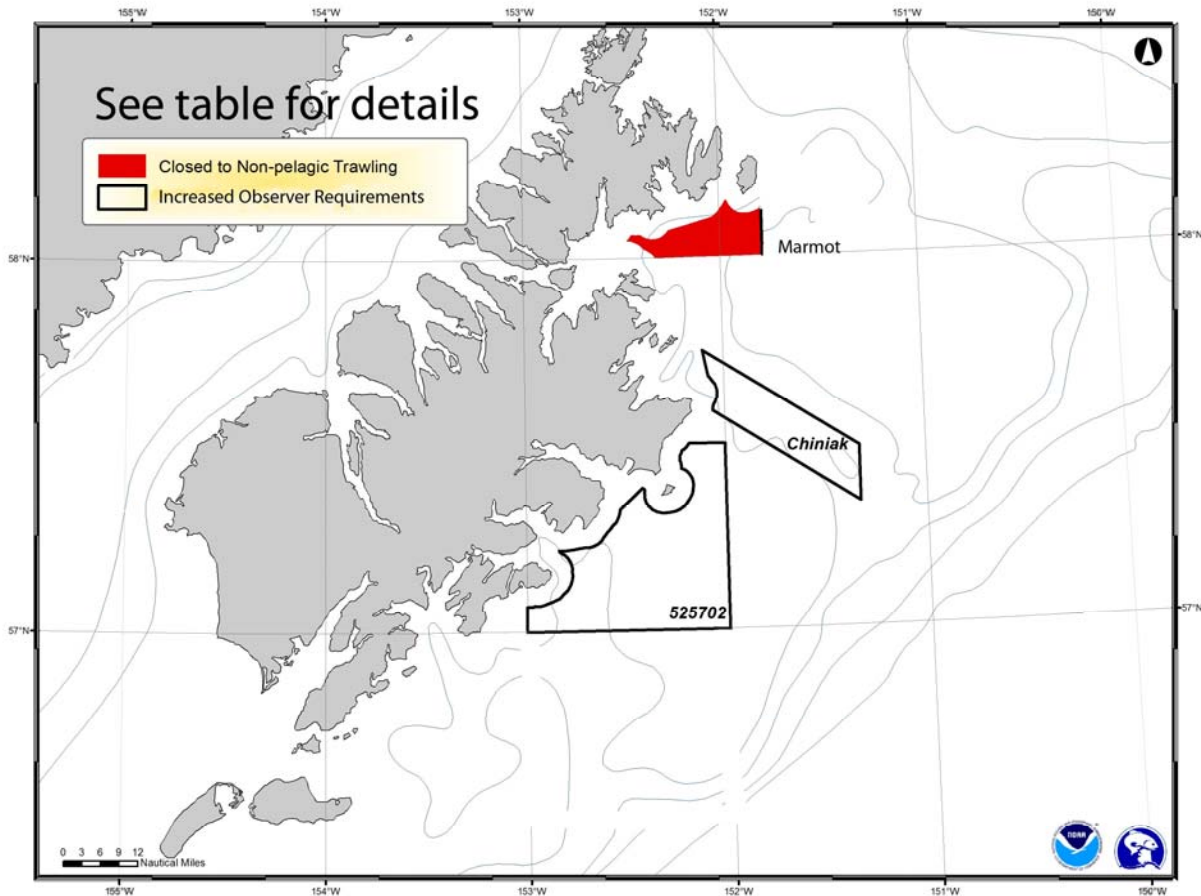

Areas:

- *ADF&G Northeast Section:* Chiniak Gully (Four corners at 152°19'34" W x 57°49'24" N by 57°29' N x 151°20' W by 57°20' N x 151°20' W by 57° x 152°9'20' W), excluding State waters (Figure 4).
- *ADF&G Eastside Section:* Statistical Area 525702 (Figure 4).

Develop a trailing amendment to require trawl vessels to use approved modified gear (e.g. trawl sweep modifications) in the Central GOA nonpelagic trawl fishery. It is expected that NMFS will initiate an iterative process similar to that used to develop trawl sweep specifications in the BSAI in order to implement the trawl sweep requirement and reduce the footprint in the GOA by bottom trawls.

Based on the Council's recommendation, NMFS, in consultation with the Council, determined that the observer options are not necessary to achieve the Council's goal to improve Tanner crab PSC data and they will not be part of the final action. Amendment 76 to the Fishery Management Plan for Groundfish

of the GOA was approved on June 7, 2012 (77 FR 15079, March 14, 2012). This amendment provides the restructured Observer Program that will improve overall catch data information for the GOA. Under the deployment plan, it is not possible to establish discrete areas with vessel specific observer requirements and maintain the random selection necessary to ensure statistically robust observations throughout the GOA. Because overall observer data will be improved, the restructured Observer Program will meet the Council’s objective to have better information on Tanner crab PSC not only in the areas described in the option but also across the GOA. The restructured observer program was implemented in early 2013.

	Trawl	Pot
Marmot Bay	Closed (vessels using pelagic trawl gear to fish for pollock are exempt)	Closed to pot gear unless 30 percent observer coverage
Chiniak Gully	Closed to nonpelagic trawl gear unless 100 percent observer coverage	
ADFG statistical area 525702		

Figure 31 Areas established around Kodiak under the preferred alternative, in which nonpelagic trawl gear is prohibited, or nonpelagic trawl and pot vessels may only fish if they carry observer coverage

6.5 Description of the fisheries

6.5.1 Groundfish fisheries in reporting area 630

The proposed action would potentially regulate vessels participating in the trawl and pot groundfish fisheries in reporting area 630 (Kodiak district) of the Central GOA regulatory area. Table 31 provides the official total catch (retained and discarded) in the groundfish fisheries, by gear type, in area 630 from 2003 through 2009. Catch by vessels using nonpelagic trawl gear represents the largest proportion of groundfish catch by gear type, approximately 60 percent on average during the time period. The primary species targeted by gear type are as follows: for nonpelagic trawl gear, flatfish (shallow-water flatfish, flathead sole, rex sole, arrowtooth flounder), Pacific cod, pollock, and rockfish; for pelagic trawl, pollock and rockfish; and for pot gear, Pacific cod.

Table 31 Official total catch (mt) in groundfish fisheries in reporting area 630, by gear type, 2003 through 2009

Year	Nonpelagic trawl	Pelagic trawl	Pot	Hook-and-line	Total
2003	51,194	11,556	2,069	10,406	75,225
2004	42,916	13,539	4,114	12,419	72,987
2005	38,719	20,622	7,408	10,308	77,056
2006	43,505	18,205	7,177	11,435	80,321
2007	46,539	17,169	6,311	10,774	80,794
2008	58,538	14,180	4,533	11,735	88,986
2009	53,078	11,327	4,507	8,952	77,864
Average 2003-2009	47,784	15,228	5,160	10,861	79,033

Source: NMFS Catch Accounting System. Data compiled by AKFIN, February 2010.

A comprehensive discussion of Tanner crab PSC in the GOA groundfish fisheries in reporting area 630 is included in Section 3.3.3. Pelagic trawl gear contributes very little to the overall PSC levels (Table 8), while nonpelagic trawl vessels are responsible for an average (over 2003 through 2009) of 83 percent of crab PSC, and pot gear for 17 percent. When PSC mortality is considered, pot gear contributes either 5 percent or 11 percent of total PSC mortality, depending on the mortality rate calculation used. The relationship of annual crab PSC and groundfish catch in these two sectors is depicted in Figure 32.

Patterns in trawl and pot groundfish fisheries

Seasonal openings for area 630 differ between fisheries, as noted in Table 33. The pollock TAC is made available seasonally, as a protection measure for Steller sea lion regulations, and the openings are limited to only one or two days in length due to the limited pollock TAC and the number of participating vessels. Pacific cod is also allocated into two seasons. Trawl harvesters tend to focus on higher value Pacific cod and pollock fisheries when they are open, and fish for flatfish at other times in the year. Halibut PSC is also allocated seasonally, and the availability of halibut PSC often determines the season length for flatfish fisheries. Halibut PSC allocated to the flatfish fisheries is shared among the deep-water (arrowtooth flounder and rex sole) and shallow-water (shallow-water flatfish and flathead sole) flatfish complexes.

Table 33 Opening dates of GOA trawl and pot target fisheries in 2008 and 2009

Target	Year	Open	Closed /Reason	Length of fishery
Arrowtooth flounder and rex sole	2009	20-Jan 1-Apr 1-Jul	3-Mar/halibut 23-Apr/halibut 31-Dec/regulations	42 days 22 days 6 months

6.5.2 Groundfish fisheries in proposed area closures

The proposed area closures under Alternatives 2 and 3 are within the 630 reporting area. In order to examine the spatial distribution of fishing at a finer scale than that of the reporting area, it is only possible to use the data collected on observed trips, as only observed hauls are associated with geographical coordinates. Consequently it is not possible to use the NMFS catch accounting database, which takes reports from observed fishing trips and extrapolates them to apply to all vessels fishing within the reporting area, to investigate the catch and PSC activity of vessels fishing within these specific areas. It is possible to get a sense for how much catch and PSC is occurring in the closed areas, however, by looking at data from observed groundfish vessels, as long as the limitations of using only data from observed vessels are kept in mind. These limitations are discussed in detail in Section 3.3.1. Only vessels that are 60 feet or longer are observed. Vessels between 60 feet and 125 feet using hook-and-line or trawl gear are only required to carry an observer for 30 percent of their fishing days, by quarter, although if they are larger than 125 feet they must have an observer onboard 100 percent of the time. Pot vessels carry an observer while 30 percent of their pots are pulled for the calendar year. Table 4 in Section 3.3.1 examines

the actual percentages of observed catch by gear type and target fishery. Overall, the pot Pacific cod target had averaged between 12 percent and 26 percent of groundfish catch observed in the Central GOA between 2004 and 2006. Many entries for the nonpelagic trawl fisheries are confidential, however a comparison may be made to the nonpelagic trawl shallow-water flatfish fishery, which averaged between 13 percent and 34 percent of catch observed between 2004 and 2007 in the same area. **Therefore it should be remembered, throughout this discussion, that the data may only represent a small proportion of fishing effort within the closed areas.**

Table 34 identifies the proportion of observed catch from reporting area 630 that was observed in each of the proposed area closures. On average, from 2001 through 2009, approximately 25 percent of observed catch occurred in the proposed closures as a whole; most of this catch occurred in 525702, followed by 525630. Only 5 percent of the total observed GOA groundfish catch occurred in Marmot and Chiniak.

Table 34 Observed groundfish catch in the proposed area closures, as a proportion of total observed groundfish catch in reporting area 630, by gear type, for 2001 through 2009

Year	Proposed area closures					Rest of 630
	Marmot	Chiniak	525702	525630	Total	
2001	0%	4%	16%	4%	24%	76%
2002	0%	1%	5%	10%	17%	83%
2003	2%	4%	10%	8%	24%	76%
2004	1%	2%	13%	3%	18%	82%

Average 2001-2009	1%	4%	12%	8%	25%	75%

Source: AKFIN Comprehensive Observer data, March 2010.

Groundfish catch in the proposed closure areas is examined by gear type in Table 35. For the most part, hook-and-line vessels are not observed to fish in the proposed area closures. The table provides the groundfish catch in each area, and by each gear type, as a percentage of total observed catch in 630 by each gear type over the combined years 2001 through 2009. As context, the final column indicates that fishing with trawl vessels constitutes the majority of groundfish catch in reporting area 630. Figure 33 illustrates the total observed catch for each gear type in reporting area 630, and how that catch is distributed inside and outside of the closed areas. For nonpelagic trawl, catch in the closed areas is approximately 29 percent of the total observed nonpelagic trawl groundfish catch in 630; for pelagic trawl, it is approximately 22 percent, and for pot vessels approximately 13 percent. In comparison, Tanner crab PSC in the closed areas (described in detail in Section 3.3.4, and specifically in Figure 23) was approximately 70 percent of the 630 total for nonpelagic trawl vessels, 33 percent for pelagic trawl, and 22 percent for pot vessels.

Table 35 Observed groundfish catch in the proposed area closures by gear type, as a proportion of total observed groundfish catch in reporting area 630 by gear type, for the combined years 2001 through 2009

Year	Proposed area closures					Rest of 630	Gear type's proportion of total groundfish catch in 630
	Marmot	Chiniak	525702	525630	Total		
Hook-and-line	**	0%	**	2%	2%	98%	7%
Nonpelagic trawl	1%	4%	13%	12%	29%	71%	64%

Figure 33 Observed groundfish catch in proposed closed areas and reporting area 630, by gear, for the combined years 2001 through 2009

Table 36 identifies the observed target fisheries for trawl and pot gear, listing catch in the proposed area closures (as a group) as a proportion of total observed catch by that gear type in reporting area 630.

Table 37 breaks down the observed catch into each of the individual proposed closure areas, comparing the whole time series (2001 through 2009) with the most recent three years (2007 through 2009). For nonpelagic trawl vessels, over 50 percent of the flatfish and pollock target fishing is observed to occur in the proposed closure areas, while only 20 percent of Pacific cod target fishing and very little rockfish is targeted in these areas. The 525702 and 525630 areas are particularly important for flatfish fishing. In terms of weight, most flatfish catch is attributed to the arrowtooth flounder target, although in recent years the shallow-water flatfish target has also been important. Approximately a third of the observed catch of nonpelagic trawl pollock target also came out of the Chiniak area closure. The Marmot closure is less important for nonpelagic trawl fishing. Pelagic trawl vessels in the areas are targeting pollock, with approximately a quarter of the observed catch coming from the proposed closures, primarily from 525702, although in recent years the Chiniak closure was also important for pollock fishing.

Table 36 Observed groundfish catch by gear type and target in the proposed closed areas, as a proportion of the total observed catch in that target, by gear type, in reporting area 630

Gear type	Target Fishery	2001	2002	2003	2004	2005	2006	2007	2008	2009	Average 2001-2009
Non-pelagic trawl	Arrowtooth Flounder	30%	18%	45%	51%	26%	65%	82%	58%	74%	50%
	Flathead Sole	93%	71%	26%	67%	6%	9%	89%	79%	78%	60%

Location of observed groundfish catch in proposed closed areas

Observed groundfish catch and Tanner crab PSC is mapped by gear type (for trawl and pot gears) in the color figures included at the end of this document, in Appendix A. As depicted in Color Figure 2, the primary density of groundfish catch for nonpelagic trawl vessels occurs in the central portions of the proposed closed areas 525702 and 525630. In comparison with Color Figure 1, it is apparent that this same area is also one where a high amount of crab PSC is observed. Color Figure 3 maps the PSC rate for nonpelagic trawl vessels (number of crab per mt groundfish catch), and while this area still has a higher PSC rate than some other parts of reporting area 630, it is nonetheless apparent that the high PSC in this area is due at least in part to the intensity of groundfish fishing that occurs in this area.

For nonpelagic trawl fisheries, a large proportion of groundfish in the various flatfish and pollock target fisheries is harvested within the proposed area closures. Sixty-five percent to 70 percent of groundfish caught in the pollock target occurs in the Chiniak and 525702 closures; 50 percent to 60 percent of groundfish in the arrowtooth flounder and flathead sole target occurs in 525702 and 525630; 50 percent of shallow-water flatfish occurs in 525702; and 60 percent to 70 percent of the rex sole target fishing occurs

in 525630. Color Figure 4, Color Figure 5, Color Figure 6, and Color Figure 7 show the distribution of groundfish catch in the arrowtooth flounder, shallow-water flatfish, flathead sole, and pollock target fisheries from 2003 through 2009. These maps are not based solely on observer data, but rather use the NMFS catch in areas database, which utilizes specific procedures to allocate a spatial reference to unobserved catch data. For arrowtooth flounder and flathead sole targets, there are areas outside of the proposed closures where a concentration of catch in those targets occurs, however for shallow-water flatfish target fisheries, there are few areas outside of the proposed area closures where significant catch occurs. For pollock, catch appears to be fairly widely distributed around Kodiak, although 525702 contains areas with high concentration of catch.

For pelagic trawl vessels, Color Figure 9 illustrates observed groundfish catch. Of fishing occurring in the proposed area closures, fishing is heaviest in area 525702, also in the central portion of that area. As is apparent in Color Figure 7, overall PSC of Tanner crab in the pelagic trawl fishery is substantially lower than for the nonpelagic trawl fleet. Color Figure 10 shows the PSC rate for pelagic trawl vessels, and PSC rates in the proposed closed area that is predominantly fished (525702) are very low.

The observed groundfish catch for pot vessels is mapped in Color Figure 11, and shows that the majority of observed pot effort occurs outside of the proposed closures. Within 525702 and 525630, the areas that are important to the pot fishery differ from those that are used by trawl vessels, based on observer data, without the concentration on the central portions of those statistical areas that is evident in trawl fishing patterns. Color Figure 12 shows that PSC in the pot fishery is highest just outside the southeastern boundary of area 525630. PSC rates for the pot fishery are mapped in Color Figure 13, and PSC rates for pot gear are generally higher than those for trawl.

Timing of observed groundfish catch in proposed closed areas

The majority of groundfish catch in the proposed area closures as a whole, and generally in reporting area 630, occurs in the period January 1 through July 31, representing between 62 percent and 75 percent of total observed catch between 2001 through 2009 (Table 38). In the Marmot closure, catch in the first half of the year encompasses almost all of the annual catch in 2001 through 2007, although in the last two years there has been a slight increase in observed catch in August to December. For Chiniak, the interannual variability of observed catch between the two periods is high, but on average, the area had a much lower proportion of catch in the first half of the year. From Table 39, one can see that this is true across all gear sectors, although the vast majority of the observed catch in the area is from nonpelagic and pelagic trawl vessels. 525702 also has a balanced proportion of catch from the January through July and August through December periods, where nonpelagic trawl catch is high in the beginning of the year, and pelagic trawl catch is high in the latter portion. Overall, area 525630, which is primarily fished by nonpelagic trawl vessels, has low usage by observed vessels in the latter half of the year.

Table 38 Proportion of annual observed groundfish catch in the proposed area closures between January 1 and July 31, 2001 through 2009

Year	Proposed area closures					Rest of 630	All of 630
	Marmot	Chiniak	525702	525630	Total		
2001	100%	38%	42%	62%	45%	87%	77%
2002	100%	81%	54%	82%	74%	78%	77%
2003	100%	30%	34%	36%	40%	74%	66%
2004	100%	78%	34%	75%	46%	76%	70%

To provide additional perspective on the timing of fisheries within the two periods described above, Table 40 breaks out the observed groundfish catch for nonpelagic trawl vessels by month. The majority of nonpelagic trawl catch in the closed areas occurs in April and July, followed by October, February, and March as important time periods. For pelagic trawl vessels, the most important month for fishing in the closed areas is October, followed by September and August, and then March and February.

Table 40 Proportion of annual observed nonpelagic trawl groundfish catch in the proposed area closures in each month, for the combined years 2001 through 2009

Area	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec

6.5.3 Participants

Table 41 identifies the number of vessels fishing for groundfish in reporting area 630, by gear type, between 2003 through 2009, as well as the number of those vessels that are attributed with having Tanner crab PSC. Table 42 shows the number of observed vessels fishing in the proposed area closures over the period 2001 through 2009. In many of the proposed areas closures, the number of vessels of a particular gear type fishing in an area in a particular year may be very low. The most observed vessels fishing in the closed areas occur in the nonpelagic trawl sector.

Table 41 Number of vessels fishing for groundfish in reporting area 630, by gear type, over the period 2003 through 2009

Gear type	Total number of vessels	Total number of vessels to which Tanner crab PSC was attributed	Vessels with PSC as percentage of total
Hook-and-line	606	317	52%
Nonpelagic trawl	74	68	94%
Pelagic trawl	53	47	89%
Pot	129	100	76%

Of observed vessels fishing in the proposed closure areas, in all years except 2002 and 2003, most vessels are between 60 feet and 124 feet LOA. Table 43 shows the proportion of groundfish catch attributable to vessels greater than 125 feet in the proposed closed areas, compared to vessels fishing in reporting area 630 as a whole. Note, observer coverage is not required on vessels less than 60 feet overall, so information about how the proposed area closures are used by these vessels is not available.

6.5.4 Dependency

This section provides estimates of economic dependency for the proposed action. The data used to estimate dependency are from Alaska Department of Fish and Game fish tickets. Unlike the observer data, fish tickets have revenue data at the statistical area level. Unfortunately, fish ticket data have some limitations. First, given that the Chiniak and Marmot areas are composed of several statistical areas, the fish ticket data used to estimate the economic dependency on these two areas would, in all likelihood, overstate that dependency, so dependency estimates for these two areas are not included in this analysis. Second, fish ticket data used to estimate dependency relies on fishermen reported harvest locations, which at times is only approximated. Finally, due to the lack of catcher processor revenue data at the statistical area, economic dependency for the catcher processor sector was not included in this section.

As indicated in the tables below, many of the catcher vessels targeting flatfish operating around Kodiak appear heavily dependent upon groundfish catch from the proposed closure areas. For example, several catcher vessels harvest more than 30 percent of their entire flatfish catch from these areas. Also, many of the owners of these vessels are residents of Kodiak; therefore it is likely that the community of Kodiak is also dependent upon the groundfish catch in the proposed closure areas. As shown in Table 44, four catcher vessels generated, on average, greater than 20 percent of their total exvessel revenue from area 525702 alone. Looking at the rest of the catcher vessels that operated in area 525702 during the 2007 through 2009 period, on average 11 vessels on average had exvessel revenue greater than 15 percent but less than 20 percent from this area; 12 vessels on average had exvessel revenue greater than 10 percent but less than 15 percent from this area; 31 vessels on average had exvessel revenue greater than 5 percent but less than 10 percent from this area; and the remaining 72 vessels on average had less than 5 percent of their exvessel revenue from this area. Looking at statistical area 525602, fewer than three vessels on average had exvessel revenue greater than 20 percent from this area; fewer than three vessels on average had exvessel revenue greater than 10 percent but less than 15 percent from this area; 13 vessels on average had exvessel revenue greater than 5 percent but less than 10 percent from this area; and 33 vessels on average had less than 5 percent of their exvessel revenue from this area.

Looking specifically at flatfish exvessel revenue in these two areas (Table 45), seven vessels on average generated greater than 30 percent of their total flatfish exvessel revenue from statistical area 525702, while five vessels on average generated greater than 30 percent of their total flatfish exvessel revenue from statistical area 525630. Another five vessels had greater than 20 percent but less than 30 percent of their total flatfish exvessel revenue from statistical area 525702; and three vessels garnered a similar amount from statistical area 525630. In addition, all but three catcher vessels operating in the statistical area 525630 during the 2007 through the 2009 period also operated in statistical area 525702. However, 23 out of the total 70 catcher vessels that operated in statistical area 525702 during the period 2007 through 2009

did not operate in statistical area 525630 during this period. This could indicate the relative importance of statistical area 525702 when compared to statistical area 525630 for the numerous catcher vessels targeting groundfish in these areas.

Table 44 Number of vessels by average percent of exvessel revenue for groundfish from statistical areas 525702 and 525630, 2007 through 2009

Average percent of ex vessel revenue from the proposed closure area during the 2007 through 2009 period*	Number of vessels

Looking at dependency from the perspective of gear, both bottom trawl and pot gear appear to rely heavily on the groundfish fisheries in the proposed closure areas. For example, vessels that targeted groundfish in statistical area 525702 during the 2007 through the 2009 period using bottom trawl gear on average received 12.2 percent of their total exvessel revenue from the statistical area (Table 46). For pot gear, dependency appears even higher at 17.6 percent of all exvessel revenue from statistical area 525702. For statistical area 525602, dependency appears slightly lower for bottom trawl gear at 5.5 percent, but significantly higher for pot gear at 25 percent (Table 47).

Looking at gross exvessel revenue by target for the proposed closure areas, those harvesting flatfish and Pacific cod appear to rely heavily on these fisheries. For example, vessels that targeted flatfish in statistical area 525702 during the 2007 through the 2009 period, on average, received 20 percent of their total gross exvessel revenue from flatfish in this statistical area (Table 48). Those targeting Pacific cod in this area, received approximately 10 percent of their total gross exvessel revenue from this statistical area. For statistical area 525630, vessels targeting flatfish received 8 percent of their total gross exvessel revenue from this area, while those targeting Pacific cod received 8.5 percent of their total gross exvessel revenue from this area (Table 49).

From a community perspective, 23 catcher vessel owners that harvested groundfish from statistical area 525702 reported their residence as Kodiak during the 2007 through 2009 period. The total gross exvessel revenue for these vessels during the 2007 to 2009 period was estimated to be \$72.3 million, of which \$5.4 million or 7.8 percent was generated from statistical area 525702 (Table 50). For statistical area 525630 (Table 51), 46 catcher vessels with owners residing in Kodiak had a total generated exvessel revenue during the 2007 to 2009 period of \$51.5 million, of which \$2.5 million or 4.9 percent was from groundfish harvested in the statistical area. Although an accurate estimate of total annual gross exvessel revenue generated from the proposed closure that is spent in the Kodiak economy is not known, it is likely that some portion of that revenue is spent in the community and, therefore, generates additional economic activity in the community.

* 2009 revenue data were not yet available for halibut IFQ

In addition to the economic activity generated from the spending of exvessel revenue in communities such as Kodiak, economic activity also occurs from the processing of groundfish harvested from the proposed closure areas. Although processing data at the statistical area level are not available, it is not unreasonable to assume that a large share of the groundfish harvested in the proposed closure areas is processed at Kodiak shore processing facilities, given the numerous and diverse processing operations available in Kodiak and the location of the proposed closure areas in relation to the community of Kodiak. Table 52 lists detailed information on total volume and value of fish landings for Kodiak for 2006, by species or species group. Clearly, the value of landings in Kodiak are dominated by salmon (30 percent), and Pacific cod (19 percent), pollock (13 percent), and halibut (12 percent), which together accounted for 75 percent of the total value of all species landed. Sablefish accounted for about 8 percent of the total, while all species of crab combined accounted for a little over 6 percent of the total, and flatfish accounted for about 6 percent of the total (arrowtooth flounder and flatfish categories combined). The remaining species or species groups, including rockfish, accounted for more than 2 percent of the total, but, as shown, several groundfish species were relatively high-volume species locally, but accounted for a relatively small proportion of the total gross value landed, due to relatively low values per pound.

Table 52 Volume and gross value of fish landed at Port of Kodiak, by species, 2006

Species	Volume Landed (pounds) ¹	Percent of Total Volume	Exvessel Value (dollars)	Percent of Total Value

Community and Social Conditions for Kodiak

Historically, Kodiak has been the base for operations in the shore-based sector of the Central GOA rockfish fisheries. Kodiak is a large community by Alaska standards and is the seventh largest community

in the State in terms of population.⁸ Accompanying this size is a relatively diversified economy compared to other fishing communities in the southwestern part of the State. In terms of direct employment in the fishery being the overriding factor in residency decisions, the population of Kodiak could be viewed as less directly tied to the fishing economy than, for example, is the case for Unalaska, Akutan, or King Cove. Much of the economic diversity seen in Kodiak, however, links back to commercial fisheries in one way or another, with commercial fishing underpinning much of the apparent diversity, generating secondary and indirect employment, and otherwise driving a wide range of related activities. For example, there is a considerable U.S. Coast Guard presence in the community. While not a direct fisheries activity, the base would likely not exist in Kodiak, and certainly not at its present size (the largest in the United States), if it were not driven by commercial fishing-related demands in both the GOA and BSAI.

The Kodiak fleet is primarily composed of multigear and multispecies boats. Vessels in this fleet usually have a handshake agreement with a shore processor for the delivery of fish. The vessel is said to “work for” the shoreplant, and sometimes the plant operators refer to “their boats,” meaning those with which working relationships exist. These vessels deliver to that plant on a regular basis. The size and composition of processor fleets vary, depending on the plant’s capacity and product mix, as noted in the processor discussion below. Most of the boats that deliver to Kodiak processors are multipurpose vessels that can change fisheries to meet the current market and fishing circumstances. For example, some vessels will switch between crab, halibut, and Pacific cod, or crab, halibut, and pollock. The size of a processor’s fleet depends on what season it is and what they are targeting at the time. It is not uncommon, however, for a plant to have a fleet of 8 to 16 boats fishing groundfish and crab. Among plants that run pollock, there is a bimodal distribution of trawl fishing power. The larger plants typically have 8 to 10 trawlers working with them, whereas the smaller plants typically have 4 or fewer trawlers in their pollock fleet. Most plants also have 6 to 10 fixed gear vessels in their fleet. Most of the fixed gear boats are pot boats fishing for Pacific cod and/or Tanner crab (when openings occur). There is a small fleet that fishes for Dungeness crab, as well.

Some information concerning the impacts of fisheries on the community can be gleaned from examining the residency information of participants in the fisheries. Participation by residency estimates can be generated for each of the primary participating sectors, catcher vessels, catcher processors, and processors. In each case, care should be taken in evaluating the importance of the estimates, as the information available to estimate participation by residence will not fully reflect the distribution of regional and local impacts. For example, a vessel owner may not reside in the community that is used as a registered mailing address. In addition, participants in all sectors likely purchase inputs and hire crew from outside of their communities of residence. In addition, impacts of similar magnitudes will have differing importance with the size of the local and regional economy. Small communities could be greatly affected by impacts that are likely to go unnoticed in large communities.

As one of the largest ports of Alaska, vessels home ported in Kodiak participate in many of the State’s largest fisheries. Nearly 550 fishing permit holders and over 190 owners of federally permitted vessels resided in Kodiak as of 2008. In excess of 98,000 metric tons of groundfish were delivered into Kodiak in 2008. Table 53 shows total landings by Kodiak-based vessels from 1995 through 2008. Table 54 shows total exvessel gross revenues of Kodiak-based vessels from 1995 through 2008. Comparing the total catch and exvessel revenues with catch and revenue from the groundfish fisheries, it is apparent that while some individually targeted groundfish (such as rockfish or sablefish) are a relatively small portion of the total fishing activity in Kodiak. Notwithstanding this apparently small contribution to overall catch of Kodiak catcher vessels, some participants report that the fishery is important to their operations. These participants suggest that the supplemental income from these individual fisheries is important to their

⁸ The six largest communities in Alaska, in order, are Anchorage, Juneau, Fairbanks, Sitka, Ketchikan, and Kenai. There are two different basic types of local governance in these communities: Anchorage, Juneau, and Sitka are unified Home Rule Municipalities (i.e., unified city/boroughs), while Fairbanks, Ketchikan, and Kenai, like Kodiak, are Home Rule Cities (Kodiak Chamber of Commerce 2004).

overall returns. As such, the fishery could also be of some importance to the trawl catcher vessel contribution to the Kodiak economy, to the extent that it is important to the operations of these Kodiak groundfish vessels.

Kodiak's shoreplants have played a significant role in the history of the community, influencing its economic and demographic patterns over the years. Even among the eight major contemporary processing plants, there is a considerable amount of diversity in the size, volume, and species processed. It is this diversification that best characterizes Kodiak's ability to weather the ebbs and flows of an industry dependent upon changes in the viability of the resource being harvested, the market itself, and past/future regulatory shifts. Locally based processors vary in product output and specialization, ranging from large quantity canning of salmon, processed at several different locations within Kodiak, to fresh and fresh-frozen products, as well as niche markets servicing the sports-fishing industry.

While the presence of local processing has been a constant in the community, individual operations have substantially different histories and have undergone a variety of changes in recent years. For example, among the large plants processing groundfish and salmon in the community, the facility now operated by Trident Seafoods centers around a converted World War II "Liberty Ship" that was reportedly brought to the community by previous owners (Alaska Packers) in the wake of the devastating 1964 earthquake to become the first plant up and running after that disaster. (This facility apparently later operated under the names All Alaskan and Tyson Seafoods, before being acquired by its present owner.) Ocean Beauty, on the other hand, operates in a facility originally built in 1911, which was the oldest and largest seafood production facility in Kodiak when it was purchased in the 1960s. In 1967, B&B Fisheries opened its

doors, which became Western Alaska Fisheries in the early 1970s, and is still in existence today. Ownership type also varies widely. For example, International Seafoods of Alaska (ISA) is a wholly owned subsidiary of True World Group, Inc., which is in turn owned by the Unification Church. In contrast, Alaska Fresh Seafoods (AFS), a smaller plant, has been in operation since 1978 and is owned, in part, by Kodiak and other Alaska fishermen.

All plants experience busy and slow periods during the year, but these peaks and valleys differ at least slightly for each processor, based upon the dependence of processor to fishery or the relationship between fleet and processor. This seasonal pattern has also changed with changes in the fisheries. For example, earlier (2004) interviews with processing plant personnel pointed out how the role of halibut has changed in terms of local processing since the implementation of the halibut IFQ management program, with three-quarters or more of all halibut going to market as a fresh product, as opposed to perhaps one-quarter before IFQs. This has not only changed the role of halibut in individual operations, it has also resulted in a different pattern of landings, with the economics of the fresh market favoring road-connected ports over Kodiak for at least some harvest areas. More recently, BSAI crab rationalization has shifted the periods when BSAI crab is run at the local processors.

With regard to the workforce among Kodiak processors, the large majority of plant workers in Kodiak are drawn from the local labor pool. While some workers still come to the community specifically for processing work opportunities, in the past 20 years, the importation of short-term workers by the processing companies themselves has become less and less common. As of 2008, among all major Kodiak plants, only Trident reports bringing workers into the community on a 6 month contract basis and providing them bunkhouse quarters, similar to the pattern seen in the years before the development of a large local workforce. In the not-too-distant past, Ocean Beauty and Western Alaska Fisheries both utilized bunkhouse facilities during peak seasons, but neither continues to do so. (Alaska Pacific Seafoods [APS] has retained a small bunkhouse, but this is used only as transitional housing for workers new to the community; ISA has a bunkhouse, but rents out spaces to workers as a more-or-less traditional landlord rather than providing living quarters as part of a room-and-board living arrangement; Western Alaska Fisheries will rent housing on a temporary basis for transient student workers during peak seasons but otherwise does not provide housing for its workers.) This high reliance on the processing workers from a local labor pool differentiates Kodiak from other major processing communities in the southwestern part of the state, such as Unalaska, Akutan, King Cove, and Sand Point. Major processors in each of these communities still retain a relatively transient labor force approach to staffing processing plants. In January 2005, however, in a departure from the local pattern, Western did hire seasonal workers from outside the community for the early peak Pacific cod season, but did not offer housing as part of the employment agreement. This ended up causing considerable concern in the community as, according to local newspaper accounts, about 80 people hired through Alaska Job Service in Anchorage arrived in the community prior to the start of the season, without having made housing arrangements (despite knowing that they needed to do so) and without sufficient resources to care for themselves prior to earning their first processing paycheck. This, in turn, proved to be a challenge for local service providers, as the unprepared workers utilized local shelters for immediate food and housing needs. While this may have been an isolated incident, it illustrates the continually changing nature of attempting to meet peak processing demands over time.

Since the program establishes a cooperative system, with strong cooperative associations with historical processors and a limited access fishery that requires deliveries to processors meeting historical processing qualifications, deliveries in the main program have continued to be made to Kodiak processors. In addition, only Kodiak processors have participated in the entry level fishery, by providing markets for entry level catcher vessels. As a result, all deliveries in the fishery have continued to be made to Kodiak under the pilot program. So, the community effects arising from implementation of the program have arisen from the changes in the Kodiak based activity. A more detailed description of the Kodiak

community is available in Appendix A of the Public Review version of the Central Gulf of Alaska Rockfish Program (NPFMC, 2010)

6.6 Analysis of Alternatives

Alternative 1 – status quo

Under Alternative 1, no area closures for protecting GOA Tanner crab would be implemented.

Alternative 2 – close areas to groundfish fishing; Suboptions 1, 2, 4, 5 – close areas to a particular gear type

Alternative 2 proposes four specific area closures to all groundfish fishing by trawl and pot gear. Component 2, Suboptions 1, 2, 4, and 5 could limit the closures to only apply to a specific gear type: trawl, pot, or nonpelagic trawl (Suboptions 4 and 5 exempt pelagic trawlers from the area closures).

Groundfish vessels that are subject to the closures will be required to forego fishing in the proposed areas. The impact on these vessels will be proportional to the extent that they rely on the area for target fishing, the extent to which they are able to offset catches foregone in the closed areas, by fishing in remaining open areas, and the net cost of making the adjustment. Based on observer data, the nonpelagic trawl fisheries will be most impacted by the area closures. Specifically, a large proportion of groundfish in the various nonpelagic trawl pollock and flatfish target fisheries is harvested within the proposed area closures. Sixty-five percent to 70 percent of groundfish caught in the nonpelagic pollock target fishery occurs in the Chiniak and 525702 closures; 50 percent to 60 percent of groundfish in the nonpelagic trawl arrowtooth flounder and flathead sole target occurs in 525702 and 525630; 50 percent of nonpelagic trawl shallow-water flatfish occurs in 525702; and 60 percent to 70 percent of the nonpelagic trawl rex sole target fishing occurs in 525630 (Table 37). For the arrowtooth flounder (Color Figure 4) and the flathead sole (Color Figure 6) targets, there are areas outside of the proposed closures where a concentration of catch in those targets occurs, however for the shallow-water flatfish target fishery (Color Figure 5), there are few areas outside of the proposed area closures where significant catches have occurred. Therefore, particularly for shallow-water flatfish, it may be difficult to fully harvest the TAC outside the proposed area closures. While for arrowtooth flounder, the alternate area of high arrowtooth catch is not one in which there is high reported crab PSC (Color Figure 1), this is not the case for flathead sole, so the overall savings in crab PSC may not be as high for this fishery.

Table 45 shows that there are 12 catcher vessels participating in the flatfish fishery that derive over 20 percent of their exvessel revenue for flatfish from 525702 and 8 vessels that derive the same proportion of their flatfish revenue from 525630. These vessels would be more severely impacted than others by the proposed closure of areas 525702 and 525630. To the extent that flatfish TACs cannot be fully harvested as a result of this alternative, there may also be impacts on the community of Kodiak and processing facilities. Table 52 identifies that flatfish represents 15 percent of total processing volume, and 6 percent of total first wholesale value.

For pelagic trawl, the biggest impact would result from closing 525702, where the western and central portions of the statistical area are important for pollock trawling. Approximately 25 percent of the groundfish catch in the pollock pelagic trawl target fishery occurred within the Marmot, Chiniak, and 525702 closures, on average, between 2007 and 2009. The pelagic trawl pollock fishery is prosecuted in other areas within reporting area 630, which would remain open to fishing (Color Figure 9). Table 46 shows that area 525702 accounted for an average of 1.51 percent of total exvessel revenue for catcher vessels. It is therefore assumed for this analysis that vessels would be able to fully harvest groundfish TACs despite the proposed area closures, albeit with potential costs. In some areas, there may be lower catch per unit effort, which would increase costs for fishermen and could result in increased PSC of crab

or other prohibited species. Depending where the vessels choose to fish, there are likely to be lower crab PSC rates in these alternate areas (Color Figure 10; Table 18). However, crab PSC in the pelagic trawl fisheries, in all years is one percent or less of the overall PSC total for reporting area 630.

For pot vessels, the proposed area closures at first appear to have a smaller impact on groundfish fishing because, according to observer data, the area is not as much fished as other parts of reporting area 630 (Color Figure 12). However, there appear to be a higher proportion of pot vessels using the proposed area closures that are unobserved (Table 15), so observer data may be less reliable for this gear type. Table 46 and Table 47 identify that an average of 42 percent of exvessel revenue from pot vessels came from the combined 525702 and 525630 statistical areas. Crab PSC within the closed areas represents a quarter of all observed crab PSC by vessels fishing with pot gear in reporting area 630 (Figure 23).

To the extent that the reduction in Tanner crab PSC from the area closures increases crab recruitment to the directed fishery, crab fishermen may also benefit from Alternative 2. However, current levels of crab PSC in the groundfish fisheries represent 0.3 percent or less of surveyed crab abundance (see Section 4.1). Numbers of crab PSC in the groundfish fisheries, and catch numbers in the directed crab fisheries are not readily comparable, as the groundfish PSC numbers include all crab (including juvenile, female, and sublegal males). Tanner crab fishery catch numbers include only legal males. It is not possible to assess the value to the directed crab fishery of crab caught as PSC in the groundfish fisheries. Catch composition of PSC is unknown, and studies differ with respect to the appropriate handling mortality rate to apply to PSC in the groundfish fisheries by gear type.

The management and enforcement considerations section (Section 5.1) recommends that VMS be used to monitor the proposed area closures. Most of the vessels that would be subject to the closures are already required to have VMS, either because they operate nonpelagic trawl gear, they participate in the Rockfish Program, or they engage in directed fishing for Pacific cod or pollock. If the proposed closures are required for sablefish hook-and-line vessels, the vessels in this fleet would need to install and operate VMS units. Purchase and installation costs for a VMS unit are approximately \$2,058. Monthly transmission fees are approximately \$63 (NMFS 2008). There is also an annual maintenance cost that is estimated at \$77.

Suboption 3 – exempt vessels using approved, modified gear

A sweep modification has been approved by the Council for implementation in the Central GOA flatfish fisheries; this modification has been shown to reduce unobserved mortality of crab from trawl sweeps (although use of the modification would not result in lower PSC in trawl nets). The average cost of the modification to fishermen using net reels, for the gear configuration used in the Central GOA is initially approximately \$12,600 approximately \$3,000 annual maintenance (NMFS 2009). For vessel using main line winches to set and haul back the modified sweeps there may also be one-time costs for modifying the vessel to accommodate the sweep modification, depending on current vessel configuration of \$20,000 to \$25,000 or higher. This cost may be offset if, as suggested, the modification extends the useful life of the sweeps, and reduces the frequency with which new gear must be purchased.

A different modification has been proposed for groundfish pot gear that would require fishermen to build an escape mechanism into the bottom of the pot to allow crab to exit. No cost specifications are available for this proposed modification, nor has it yet been tested by agency personnel.

Assuming the logistics of approving modified gear for regulatory implementation can be addressed, vessels that habitually use the proposed closure areas would have the option of paying for the installation and annual costs of using modified gear as an alternative to being displaced from their fishing grounds. Those vessels that perceive the benefit (e.g., net revenue) of retaining access to these areas to be less than the cost of the modified gear (for example, see Table 44 and Table 45 for number of vessels with a low

percentage of exvessel revenue from the proposed area closures) may choose not to modify their gear in order to participate in the proposed closure areas.

Option 1 or 2 – year round or seasonal closure

The majority of groundfish catch for all gear types occurs in January through July, which is the seasonal period identified in Option 2 (Table 39). For gears that account for almost all of the Tanner crab PSC (nonpelagic trawl and pot gears), 75 percent and 58 percent of groundfish catch is caught in the January to July period, respectively, compared to 79 percent and 74 percent of Tanner crab PSC. Under Option 2, the seasonal closure, adverse impacts from the area closures on groundfish fishermen would be reduced, as vessels could fish in the areas for the remainder of the year. This would be especially beneficial for the nonpelagic trawl fleet fishing in the Chiniak area, where 58 percent of observed catch is occurs in August through December.

Alternative 3 – close areas to groundfish fishing unless vessels have increased observer coverage

Alternative 3 would allow fishing in the proposed closure areas by vessels using trawl gear only if they carry an observer 100 percent of the days they conduct directed fishing for groundfish in these areas. All vessels using pot gear to directed fish for groundfish would be required to have 30 percent observer coverage for any fishing trip where any catch occurred inside these areas. In addition, observer coverage for any trip where fishing occurred inside these areas could not be used to fulfill the 30 percent observer coverage for trips that occurred outside of these areas.

Alternative 3 would increase costs to the owners of any vessel that continued to fish in the closure areas that are not already required to have 100 percent or greater observer coverage. The category of vessels that could incur increased costs are (1) vessels less than 60 feet LOA currently required to have no observer coverage, and (2) vessels currently required to have 30 percent observer coverage. This section provides an estimate of those increased observer coverage costs.

The three statistical areas that are fully within the proposed closure areas are 525702, 525630, and 525807. The statistical areas that overlap with the proposed closure areas are 515802, 515730, 525732, and 515700 (see Figure 3).

Catcher/processors: From 2001 through 2009, thirteen catcher/processors reported harvest from the three ADF&G statistical areas fully within the proposed closure areas. All of these catcher/processors reported using nonpelagic trawl gear in these areas and two reported also using pelagic trawl gear in the areas. Nine of these catcher/processors are 125 feet LOA or greater. In addition, three of the four catcher/processors between 60 feet and 125 feet LOA are Amendment 80 vessels, so are required to carry at least one observer while harvesting or processing groundfish in the GOA. These twelve catcher/processors would not incur increased costs for observer coverage under Alternative 3, because they already are required to have at least 100 percent observer coverage in all of their groundfish fisheries.

One catcher/processor between 60 feet and 125 feet LOA reported catch from the proposed closure areas. This vessel would be in the 30 percent observer coverage category unless it was fishing under the Rockfish Program. If it conducts fishing inside these areas in the future, under any fishery that doesn't require 100 percent observer coverage, this catcher/processor would incur additional costs for observer coverage as a result of Alternative 3. However, the days this catcher/processor fished in these areas in the past is confidential, so no specific estimates of the increase in observer coverage costs by the vessel can be provided in this RIR.

No catcher/processors using pot gear reported fishing in the three ADF&G statistical areas fully within the proposed closure areas between 2001 and 2009.

Catcher vessels: ADF&G fish tickets from 2001 through 2009 were examined to identify deliveries from catcher vessels for which vessel operators reported fishing in any of the ADF&G statistical areas within or overlapping with the proposed closure areas. Using fish tickets provides information for areas larger than the proposed closure areas, so may overestimate the number of catcher vessels that have historically fished in the proposed closure areas and the days fished in those areas. However, the smallest and most defined areas available on fish tickets are the ADF&G statistical areas, so this is the best available data for estimating the potential cost of increased observer coverage requirements for catcher vessels under Alternative 3.

Table 56 summarizes the number of catcher vessels and days fished in 2001 through 2009, by vessel length and observer coverage category, for trips where fishing occurred in at least one of the seven statistical areas listed above. The days fished reported on the fish tickets starts from the time gear is deployed to when catch is offloaded from the vessel. Data on number of days fished in categories with fewer than 4 vessels is confidential, so is not presented in the table.

Many vessels used both pelagic and nonpelagic trawl gear, so are represented in both sections of Table 56. For example, in 2009, a total of 37 vessels reported using trawl gear in at least one of these seven ADF&G statistical areas. Thirty two of these vessels reported using nonpelagic trawl gear and 34 reported using pelagic trawl gear.

Table 57 provides an estimate of the increased costs that could accrue as a result of the observer coverage requirements under Alternative 3. The information in Table 57 is based on the number of vessels in each category and number of days fished in 2009. If observer coverage is required, the observer ends up being onboard the vessel during both transit and fishing times. Therefore, additional days are added to the number of days fished from the fish tickets to represent days transiting to the fishing grounds. From the fish ticket data, the average number of days fished per trip is 1.99 for vessels using trawl gear and 2.31 for vessels using pot gear. For purposes of this analysis an average of 2 days fished per trip is used for both gear types. Transit time from Kodiak to the proposed closure areas could range from several hours to a day. An additional day is added to each trip represented by the fish ticket data to account for transit time. For example, the 1,018 fishing days for vessels between 60 feet and 125 feet LOA is divided by 2 (average fishing days per trip from fish tickets) to obtain an estimate of the total trips (509). Then, an additional day per trip is added to estimate the number of days that an observer would be required to be onboard these vessels ($1,018 + 509 = 1,527$). The total days from departure from Kodiak to offloading of the vessel is used to calculate observer coverage costs in Table 57. Estimated average cost per vessel is determined by dividing the cost for all vessels by the number of vessels in each category.

Total cost in Table 57: There are two components to the estimated increased cost of the observer coverage requirements in Alternative 3. Column B in Table 57 estimates the cost of the increased days of observer coverage that would be required under Alternative 3. That is, the increase in costs from 0 percent or 30 percent to 100 percent for vessels using trawl gear, and the increase from 0 percent to 30 percent for vessels using pot gear. Column C provides the estimated total increase in cost under Alternative 3, which, for vessels currently in the 30 percent coverage category, also includes the current observer coverage costs in Column A because they would no longer be able to use current observer coverage for fishing inside the proposed closure areas to fulfill their 30 percent coverage requirements outside of the closure areas.

Less than 60 feet trawl catcher vessels: The one vessel less than 60 feet LOA fishing with nonpelagic trawl gear would incur the full cost of carrying an observer for all of the days fished in these areas.

However, the number of days fished in these areas is confidential, so no estimate of increased cost can be displayed in Table 57.

60 feet – 125 feet trawl catcher vessels: Estimated costs of current observer coverage requirements for the 37 vessels using trawl gear in these seven ADF&G statistical areas in 2009 are broken out separately for the 32 vessels that reported 1,018 days fishing in the areas, using nonpelagic gear, and the 34 vessels that reported 56 days fishing using pelagic trawl gear. Current observer coverage costs in Column A were determined by (1) adding transit days to estimate the total number of fishing days, and (2) multiplying the total fishing days by .3 (30 percent of the days) and by \$366 (the estimated cost per day of providing a NMFS-certified observer onboard a vessel). For example, for the vessels reporting nonpelagic gear, the estimated costs of observer coverage from the 1,527 days fished \$167,665 ($1,527 * .3 * 366$). This estimate is divided by 32 to estimate the average cost per vessel of current observer coverage requirements for fishing inside these areas (\$5,240).

The additional cost of increasing observer coverage to 100 percent for the 32 catcher vessels that used nonpelagic gear while fishing inside the proposed closure areas is determined by estimating the cost of providing an observer for the remaining 70 percent of the total fishing days in the seven ADF&G areas. ($\$391,217 = 1,527 * .7 * \366).

The estimated total increase in costs for these vessels under Alternative 3 is the full cost of 100 percent observer coverage inside these areas (\$558,882 or an average of \$17,465 per vessel).

The estimated increase in cost under Alternative 3 for vessels using pelagic trawl gear is a total of \$30,744 or about \$900 per vessel. Because most of the 37 vessels using trawl gear in these areas in 2009 used both nonpelagic and pelagic trawl gear, the total cost of the increased observer coverage requirements for many trawl vessels between 60 feet and 125 feet LOA would be the sum of the cost estimates for nonpelagic and pelagic trawl gear (\$589,626 or an average of \$15,936 for the 37 vessels between 60 feet and 125 feet LOA using trawl gear).

Vessels using pot gear: Although observer coverage for vessels using pot gear is based on the number of pot retrievals, information about pot retrievals inside the seven ADF&G statistical areas is not available from the fish tickets. Therefore, the estimates in Table 57 of the cost of observer coverage for vessels using pot gear is based on the number of days that vessel operators reported fishing in any one of the seven ADF&G statistical areas.

Less than 60 feet LOA pot catcher vessels: The 12 vessels less than 60 feet LOA fishing with pot gear would incur the full cost of carrying an observer for 30 percent of the estimated 308 fishing days in these areas. The total cost for that observer coverage would be \$33,764 (average per vessel of \$2,814).

60 feet – 125 feet pot catcher vessels: The 11 vessels using pot gear currently required to have 30 percent observer coverage would continue to be required to carry 30 percent observer coverage. Current observer coverage costs for fishing inside these seven ADF&G statistical areas, based on 2009 fishing activity, is estimated to be \$22,948 for the 11 vessels ($209 \text{ days} * .3 * 366$). That is an average of \$2,086 per vessel. These vessels would not be required to obtain additional observer coverage days to continue to fish inside these areas, so the estimate for additional coverage days in Colum B is zero. However, because these vessels could no longer use the 30 percent observer coverage inside the proposed closure areas to apply towards the 30 percent observer coverage requirements outside the closure area, Alternative 3 could increase their total cost of observer coverage in all of their fisheries the full amount of their current observer coverage costs.

Additional observer coverage costs: In addition to daily costs of carrying an observer while transiting or fishing, starting in 2010, vessel owners carrying observers out of Kodiak have been required to pay for

observer coverage costs for the days observers must be on standby in Kodiak, waiting for weather or fishery openings. Vessel owners are cooperating to use observer coverage as efficiently as possible. However, any increase in the number of observer days required likely will increase the number of days observers are on standby, thereby increasing the total cost of the observer coverage requirements under Alternative 3.

Importance of these seven ADF&G statistical areas: All fish tickets for the vessels that fished within these seven ADF&G statistical areas in 2009 also were examined to estimate the percentage of total reported fishing days that occurred within these areas. These seven ADF&G statistical areas represented from 2 percent to 68 percent of all of the fishing days for the catcher vessels from 60 feet to 125 feet using trawl gear, from 1 percent to 54 percent for vessels <60 feet LOA using pot gear, and from 8 percent to 77 percent for vessels 60 feet to 125 feet LOA using pot gear.

Cost of Alternative 3 to NMFS: NMFS estimates that each day of additional observer coverage costs the agency \$130. Based on 2009 data, NMFS may expect an increase of 2,128 observer days as a result of Alternative 3 (the sum of total fishing days in Table 57). These additional observer coverage days would cost NMFS approximately \$277,000, a cost that is not currently identified in NMFS's budget.

¹# days for observer coverage = days fished from ADF&G fish tickets plus additional amount for transit days.

²A total of 37 vessels reported using trawl gear in the seven ADF&G statistical areas in 2009. Thirty-two of these vessels reported using nonpelagic trawl gear and 34 reported using pelagic trawl gear.

na = not applicable

PREFERRED ALTERNATIVE – close Marmot Bay (statistical area 525807) year-round to nonpelagic trawl fishing, and require pot vessels fishing in the area to have 30 percent observer coverage. Close the Chiniak Gully and 525630 areas to trawl and pot fishing, unless vessels have 100 percent and 30 percent observer coverage, respectively.

Under the preferred alternative, a year-round closure area is established in Marmot Bay (statistical area 525807) for trawl vessels, with an exception for directed fishing for Pollock with pelagic trawl gear. The impact on these vessels will be proportional to the extent that they rely on the area for target fishing, the success they have in offsetting forgone catch from the closed areas in the remaining open areas, and the net cost of making the adjustment. Based on observer data, only a small percentage of the total nonpelagic trawl target fisheries have operated in the Marmot Bay closure area in recent years. The area has been used for some flatfish and pollock fishing. Only 2 percent to 3 percent of the average observed groundfish catch of shallow-water flatfish occurred in Marmot Bay (Table 37). As this area represents only a small proportion of the total observed pollock and flatfish catch, and does not represent an area where the concentration of pollock and flatfish catch historically occurred, it is anticipated that vessels will be able to catch the TAC in neighboring areas.

To the extent that the reduction in Tanner crab PSC in the Marmot Bay area increases crab recruitment to the target fishery, crab fishermen may also benefit from this closure. However, current levels of crab PSC in the groundfish fisheries represent 0.3 percent or less of surveyed crab abundance (see Section 4.1). Numbers of crab PSC in the groundfish fisheries, and catch numbers in the directed Tanner crab fisheries are not readily comparable, as the groundfish PSC numbers include all crab (including juvenile, female, and sublegal males), while crab fishery catch numbers include only legal males. It is not possible to assess

the value to the directed crab fishery of crab PSC in the groundfish fisheries. Catch composition of PSC is unknown, and studies differ with respect to the appropriate handling mortality rate to apply to PSC in the groundfish fisheries, by gear type.

The management and enforcement considerations section (Section 5.1) recommends that VMS be used to monitor the proposed area closures. All of the vessels that would be subject to the Marmot Bay closure are already required to have VMS, because they operate nonpelagic trawl gear.

As with Alternative 3, the Council's Preferred Alternative would increase costs to the owners of any nonpelagic trawl vessel that continued to fish in the closure areas that are not already required to have 100 percent or greater observer coverage. For pot vessels that continue to fish these areas, the additional cost would reflect the 30 percent required coverage. The category of vessels that could incur increased costs are (1) vessels less than 60 feet LOA currently required to have no observer coverage, and (2) vessels currently required to have 30 percent observer coverage. The incurred costs are slightly less than are estimated above, because Alternative 3 includes nonpelagic trawl vessels that may have fished in the Marmot Bay closure area, which is permanently closed under the preferred alternative, and also includes required observer coverage in statistical area 525630, which is not required in the Preferred Alternative.

As described in description of the alternatives and in Section 5, the proposed action will not include the observer coverage portion of Alternative 3, and therefore the costs of increased coverage or potential forgone fishing in the observer areas would not occur.

Net benefit to the Nation

The net benefit to the Nation of the proposed alternatives cannot be readily quantified. The alternatives are not likely to result in forsaken groundfish harvest, as the groundfish TACs will likely be harvested in neighboring areas. There may be an increased cost associated with the displaced groundfish harvest, particularly for flatfish (and potentially pollock), due to lower catch per unit effort rates elsewhere. Some benefits may accrue to the Nation through the continued conservation and protection of Tanner crab stocks, as a source of mortality and injury from the groundfish fisheries is reduced. Based on all available scientific data and commercial information, the Council concludes that the conservation and protection benefits to the GOA Tanner crab resource, as prescribed within MSA, exceed the attributable costs to the industry, dependent communities, Agency, and interested public of implementing the Preferred Alternative. That is, the preferred alternative is expected to yield a net benefit to the Nation.

7 Initial Regulatory Flexibility Analysis

7.1 Introduction

This IRFA evaluates the impacts on directly regulated small entities of the proposed action to close areas around Kodiak Island to protect *C. bairdi* crab. Included in the alternatives under consideration are options to apply the closures year round or seasonally, and to pot and/or trawl gear types. Additionally, some vessels may be exempted from the area closures if they meet specific conditions such as using approved gear modifications, or an observer coverage requirement.

7.2 The purpose of an IRFA

The RFA, first enacted in 1980, was designed to place the burden on the government to review all regulations to ensure that, while accomplishing their intended purposes, they do not unduly inhibit the ability of small entities to compete. The RFA recognizes that the size of a business, unit of government, or nonprofit organization frequently has a bearing on its ability to comply with a federal regulation. Major goals of the RFA are (1) to increase agency awareness and understanding of the impact of their regulations on small business, (2) to require that agencies communicate and explain their findings to the public, and (3) to encourage agencies to use flexibility and to provide regulatory relief to small entities. The RFA emphasizes predicting impacts on small entities as a group distinct from other entities and on the consideration of alternatives that may minimize the impacts while still achieving the stated objective of the action.

On March 29, 1996, President Clinton signed the Small Business Regulatory Enforcement Fairness Act. Among other things, the new law amended the RFA to allow judicial review of an agency's compliance with the RFA. The 1996 amendments also updated the requirements for a final regulatory flexibility analysis, including a description of the steps an agency must take to minimize the significant (adverse) economic impacts on small entities. Finally, the 1996 amendments expanded the authority of the Chief Counsel for Advocacy of the SBA to file *amicus* briefs in court proceedings involving an agency's alleged violation of the RFA.

In determining the scope or "universe" of the entities to be considered in an IRFA, NMFS generally includes only those entities that can reasonably be expected to be directly regulated by the proposed action. If the effects of the rule fall primarily on a distinct segment, or portion thereof, of the industry (e.g., user group, gear type, geographic area), that segment would be considered the universe for the purpose of this analysis. NMFS interprets the intent of the RFA to address negative economic impacts, not beneficial impacts, and thus such a focus exists in analyses that are designed to address RFA compliance.

Data on cost structure, affiliation, and operational procedures and strategies in the fishing sectors subject to the proposed regulatory action are insufficient, at present, to permit preparation of a "factual basis" upon which to certify that the preferred alternative does not have the potential to result in "significant economic impacts on a substantial number of small entities" (as those terms are defined under RFA). Because based on all available information it is not possible to "certify" this outcome, should the proposed action be adopted, a formal IRFA has been prepared and is included in this package for Secretarial review.

7.3 What is required in an IRFA?

Under 5 U.S.C., Section 603(b) of the RFA, each IRFA is required to contain:

- § A description of the reasons why action by the agency is being considered;
- § A succinct statement of the objectives of, and the legal basis for, the proposed rule;
- § A description of and, where feasible, an estimate of the number of small entities to which the proposed rule will apply (including a profile of the industry divided into industry segments, if appropriate);
- § A description of the projected reporting, recordkeeping and other compliance requirements of the proposed rule, including an estimate of the classes of small entities that will be subject to the requirement and the type of professional skills necessary for preparation of the report or record;
- § An identification, to the extent practicable, of all relevant federal rules that may duplicate, overlap or conflict with the proposed rule;
- § A description of any significant alternatives to the proposed rule that accomplish the stated objectives of the proposed action, consistent with applicable statutes, and that would minimize any significant adverse economic impact of the proposed rule on small entities. Consistent with the stated objectives of applicable statutes, the analysis shall discuss significant alternatives, such as—
 1. The establishment of differing compliance or reporting requirements or timetables that take into account the resources available to small entities;
 2. The clarification, consolidation, or simplification of compliance and reporting requirements under the rule for such small entities;
 3. The use of performance rather than design standards; and
 4. An exemption from coverage of the rule, or any part thereof, for such small entities.

7.4 What is a Small Entity?

The RFA recognizes and defines three kinds of small entities: (1) small businesses, (2) small non-profit organizations, and (3) small government jurisdictions.

Small businesses. Section 601(3) of the RFA defines a “small business” as having the same meaning as “small business concern” which is defined under Section 3 of the Small Business Act. “Small business” or “small business concern” includes any firm that is independently owned and operated and not dominant in its field of operation. The SBA has further defined a “small business concern” as one “organized for profit, with a place of business located in the United States, and which operates primarily within the United States or which makes a significant contribution to the U.S. economy through payment of taxes or use of American products, materials or labor...A small business concern may be in the legal form of an individual proprietorship, partnership, limited liability company, corporation, joint venture, association, trust or cooperative, except that where the firm is a joint venture there can be no more than 49 percent participation by foreign business entities in the joint venture.”

The SBA has established size criteria for all major industry sectors in the United States, including fish harvesting and fish processing businesses. A business involved in fish harvesting is a small business if it is independently owned and operated and not dominant in its field of operation (including its affiliates) and if it has combined annual receipts not in excess of \$4.0 million for all its affiliated operations worldwide. A seafood processor is a small business if it is independently owned and operated, not dominant in its field of operation, and employs 500 or fewer persons on a full-time, part-time, temporary, or other basis, at all its affiliated operations worldwide. A business involved in both the harvesting and processing of seafood products is a small business if it meets the \$4.0 million criterion for fish harvesting operations. Finally a wholesale business servicing the fishing industry is a small business if it employs 100 or fewer persons on a full-time, part-time, temporary, or other basis, at all its affiliated operations worldwide.

The SBA has established “principles of affiliation” to determine whether a business concern is “independently owned and operated.” In general, business concerns are affiliates of each other when one concern controls or has the power to control the other or a third party controls or has the power to control both. The SBA considers factors such as ownership, management, previous relationships with or ties to another concern, and contractual relationships, in determining whether affiliation exists. Individuals or firms that have identical or substantially identical business or economic interests, such as family members, persons with common investments, or firms that are economically dependent through contractual or other relationships, are treated as one party with such interests aggregated when measuring the size of the concern in question. The SBA counts the receipts or employees of the concern whose size is at issue and those of all its domestic and foreign affiliates, regardless of whether the affiliates are organized for profit, in determining the concern’s size. However, business concerns owned and controlled by Indian Tribes, Alaska Regional or Village Corporations organized pursuant to the Alaska Native Claims Settlement Act (43 U.S.C. 1601), Native Hawaiian Organizations, or Community Development Corporations authorized by 42 U.S.C. 9805 are not considered affiliates of such entities, or with other concerns owned by these entities solely because of their common ownership.

Affiliation may be based on stock ownership when (1) a person is an affiliate of a concern if the person owns or controls, or has the power to control 50 percent or more of its voting stock, or a block of stock which affords control because it is large compared to other outstanding blocks of stock, or (2) if two or more persons each owns, controls or has the power to control less than 50 percent of the voting stock of a concern, with minority holdings that are equal or approximately equal in size, but the aggregate of these minority holdings is large as compared with any other stock holding, each such person is presumed to be an affiliate of the concern.

Affiliation may be based on common management or joint venture arrangements. Affiliation arises where one or more officers, directors or general partners control the board of directors and/or the management of another concern. Parties to a joint venture also may be affiliates. A contractor or subcontractor is treated as a participant in a joint venture if the ostensible subcontractor will perform primary and vital requirements of a contract or if the prime contractor is unusually reliant upon the ostensible subcontractor. All requirements of the contract are considered in reviewing such relationship, including contract management, technical responsibilities, and the percentage of subcontracted work.

Small non-profit organizations. The RFA defines “small organizations” as any not-for-profit enterprise that is independently owned and operated and is not dominant in its field.

Small governmental jurisdictions. The RFA defines small governmental jurisdictions as governments of cities, counties, towns, townships, villages, school districts, or special districts with populations of fewer than 50,000.

7.5 What is this Action?

The alternatives evaluated in this analysis were adopted by the Council in October 2009, and modified during initial review in April 2010.

Alternative 1: Status Quo – No action

Alternative 2: Close the areas specified below to pot and trawl groundfish fishing.

Component 1: Area definition

ADF&G Northeast Section

Option 1: Statistical Area 525807 and the area east of Statistical Area 525807 north of 58 degrees latitude, south of 58 degrees 15 min. latitude and west of 151 degrees 30 min. longitude.

Option 2: Chiniak Gully (Four corners at 152°19'34" W x 57°49'24" N by 57°29' N x 151°20' W by 57°20' N x 151°20' W by 57° x 152°9'20' W), excluding State waters

ADF&G Eastside Section

Option 3: Statistical Area 525702

ADF&G Southeast Section

Option 4: Statistical Area 525630

Component 2: Closure timing

Option 1: Year round

Suboption 1: trawl gear

Suboption 2: pot gear

Suboption 3: Vessels using approved, modified gear would be exempt from closures (e.g., trawl sweep modifications or pot escape mechanisms).

Suboption 4: Vessels using pelagic trawl gear would be exempt from closures

Suboption 5: Vessels using pelagic trawl gear to directed fish for pollock would be exempt from the closures

Option 2: Seasonally (January 1 – July 31)

Suboption 1: trawl gear

Suboption 2: pot gear

Suboption 3: Vessels using approved, modified gear would be exempt from closures (e.g., trawl sweep modifications or pot escape mechanisms).

Suboption 4: Vessels using pelagic trawl gear would be exempt from closures

Suboption 5: Vessels using pelagic trawl gear to directed fish for pollock would be exempt from the closures

Alternative 3: In order to fish in the areas specified below, require 100 percent observer coverage on all trawl groundfish vessels and 30 percent observer coverage on all pot groundfish vessels less than 125 feet. Note, fishing days and observer coverage in these areas would be separate from, and not count towards, meeting a vessel's overall 30 percent groundfish observer coverage requirement.

Area definition

ADF&G Northeast Section

Option 1: Statistical Area 525807 and the area east of Statistical Area 525807 north of 58 degrees latitude, south of 58 degrees 15 min. latitude and west of 151 degrees 30 min. longitude.

Option 2: Chiniak Gully (Four corners at 152°19'34" W x 57°49'24" N by 57°29' N x 151°20' W by 57°20' N x 151°20' W by 57° x 152°9'20" W), excluding State waters

ADF&G Eastside Section

Option 3: Statistical Area 525702

ADF&G Southeast Section

Option 4: Statistical Area 525630

Note, the options and suboptions under Alternatives 2 and 3 are not intended to be mutually exclusive, and may be applied in combination.

Figure 34 Area closures around Kodiak Island considered in Alternatives 2 and 3

7.5.1 Council's preferred alternative

In October 2010, the Council adopted the following recommendations as their preferred alternative for this action. The recommendations combine elements of both Alternatives 2 and 3.

Close the area specified below to trawl groundfish fisheries, and require observer coverage for the pot groundfish fishery.

Area definition:

ADF&G Northeast Section: Statistical Area 525807 and the area east of Statistical Area 525807 north of 58 degrees latitude, south of 58 degrees 15 min. latitude N. and west of the longitude line extending north from the eastern boundary of the Type 1 red king crab closure area (Figure 4).

Closure timing: Year round

Vessels using pelagic trawl gear to directed fish for pollock would be exempt from the closures

Observer coverage for pot groundfish fishery

In order to fish in the area, require 30 percent observer coverage on all pot groundfish vessels less than 125 feet. Note, fishing days and observer coverage in these areas would be separate from, and not count towards, meeting a vessel's overall 30 percent groundfish observer coverage requirement. The Council encourages the agency to incorporate, to the extent possible, in the new fee-based observer program, an observer deployment strategy that ensures adequate coverage to establish statistically robust observations in the area described.

Require observer coverage for the nonpelagic trawl and pot groundfish fisheries in the areas specified below

In order to fish in the areas specified below, require 100 percent observer coverage on all nonpelagic trawl groundfish vessels and 30 percent observer coverage on all pot groundfish vessels less than 125 feet. Note, fishing days and observer coverage in these areas would be separate from, and not count towards, meeting a vessel's overall 30 percent groundfish observer coverage requirement. The Council encourages the agency to incorporate, to the extent possible, in the new fee-based observer program, an observer deployment strategy that ensures adequate coverage to establish statistically robust observations in the areas described below.

Areas:

- *ADF&G Northeast Section:* Chiniak Gully (Four corners at 152°19'34" W x 57°49'24" N by 57°29' N x 151°20' W by 57°20' N x 151°20' W by 57° x 152°9'20' W), excluding State waters (Figure 4).
- *ADF&G Eastside Section:* Statistical Area 525702 (Figure 4).

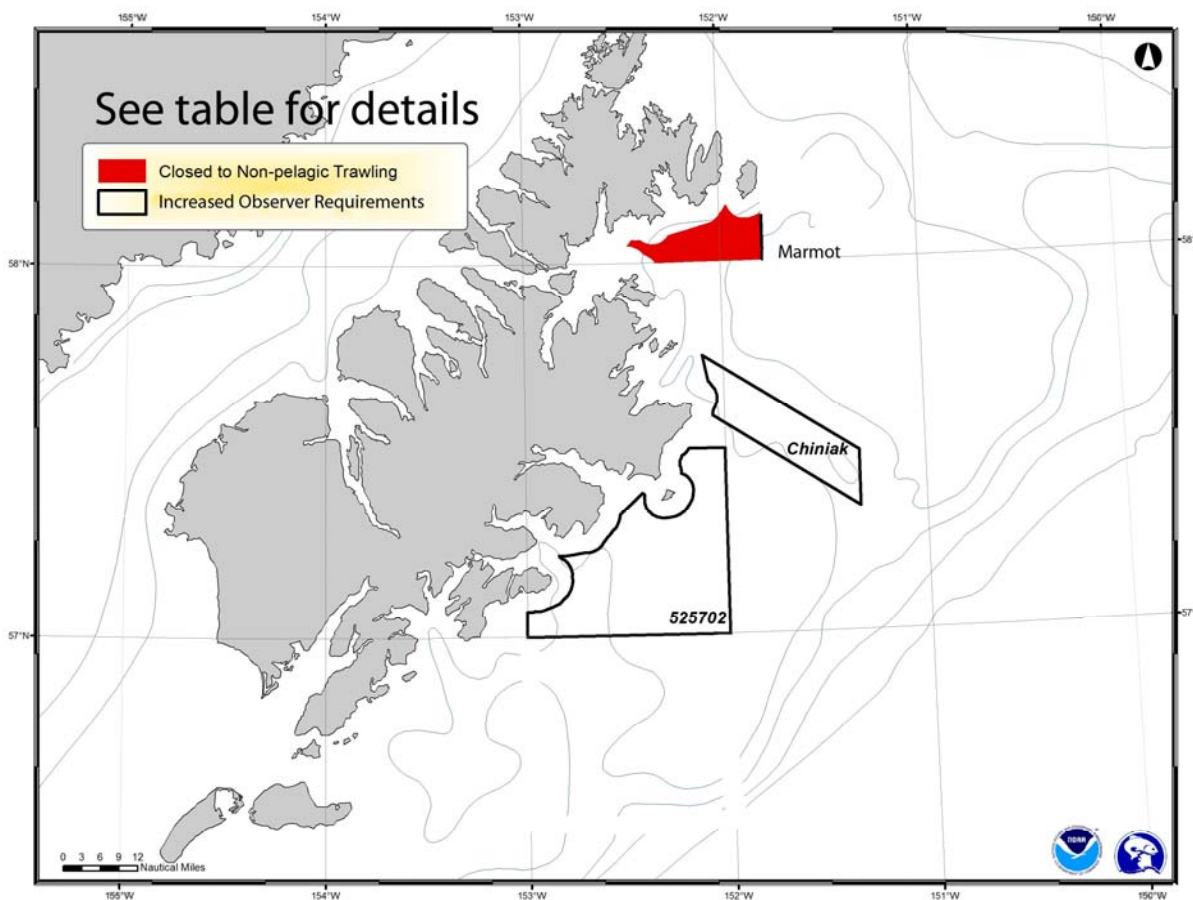

Develop a trailing amendment to require trawl vessels to use approved modified gear (e.g., trawl sweep modifications) in the Central GOA nonpelagic trawl fishery. It is expected that NMFS initiate an iterative process similar to that used to develop trawl sweep specifications in the BSAI in order to implement the trawl sweep requirement and reduce the footprint in the GOA by bottom trawls.

In April 2012, the Council recommended vessels using nonpelagic trawl gear to target flatfish in the Central GOA to use approved modified gear to reduce the potential adverse effects of nonpelagic trawl gear on benthic habitat and to reduce unobserved Tanner crab injury and mortality. In the GOA, fishing

for flatfish includes vessels targeting shallow-water flatfish, deep-water flatfish, arrowtooth flounder, rex sole, and flathead sole. These species and species groups are defined in the annual groundfish harvest specification proposed and final rules each year.

Studies in the Bering Sea (BS) have shown that elevating the trawl sweep can reduce trawl sweep impacts effects on *C. bairdi*, *C. opilio* and red king crabs by reducing the unobserved mortality of these species. In addition, elevating the trawl sweep can reduce impacts on benthic organisms, such as basketstars and sea whips. Further research was conducted in 2011 in the GOA to identify the appropriate standards for the elevated trawl sweeps to meet the Council's desired performance standard, and to identify and resolve any implementation issues. Field testing of the modified gear demonstrated that the elevated trawl sweeps can meet the standards adopted for the Bering Sea subarea (BS) flatfish fishery (75 FR 61642, October 6, 2010) and can be used in the Central GOA flatfish fishery.

Based on the Council's recommending these increased observer coverage requirements either under this action or under the restructured observer program, NMFS, in consultation with the Council, decided not to pursue the increased observer coverage requirements described herein as the restructured observer program was implemented in 2013 (77 FR 70062, November 21, 2012), the restructured observer program is anticipated to meet the Council's desire more accurate and reliable information on fishing activities. Details of the restructured observer program are available in the proposed rule (77 FR 23326, April 18, 2012). The restructured observer program would improve the quality of fisheries data, including the catch information for Tanner crab in the groundfish fisheries. Vessels under the restructured observer program would be either fully or partially observed. A randomized system for the assignment of observer coverage throughout the GOA for partially observed vessels would be used to reduce potential bias in the observer data. Selecting locations for increased observer coverage would reduce the ability to randomize observer assignments and therefore potentially bias observer data. This would not meet the Council's intent to improve the quality of observer information under Amendment 76. For these reasons, increased observer coverage in specific areas under Amendment 89 will not be pursued. It was the intent of the Council to recommend increased observer coverage in the event the amendments restructuring the observer program were disapproved or if implementation of the restructured observer program was delayed.

	Trawl	Pot
Marmot Bay	Closed (vessels using pelagic trawl gear to fish for pollock are exempt)	Closed to pot gear unless 30 percent observer coverage
Chiniak Gully	Closed to nonpelagic trawl gear unless 100 percent observer coverage	
ADFG statistical area 525702		

Figure 35 Areas established around Kodiak under the preferred alternative, in which nonpelagic trawl gear is prohibited or nonpelagic trawl and pot vessels may only fish if they carry observer coverage

7.6 Objectives and Reasons for Considering the Proposed Action

The Council formulated a problem statement in October 2009, to initiate this analysis, and revised it in April and October 2010:

Tanner crab are a prohibited species in the Gulf of Alaska (GOA) groundfish fisheries. Directed fisheries for Tanner crab in the GOA are fully allocated under the current limited entry system. No specific conservation measures exist in the GOA to address adverse interactions with Tanner crab by trawl and fixed gear sectors targeting groundfish and low observer coverage in GOA groundfish fisheries limits confidence in

the assessment of Tanner crab bycatch in those fisheries, and a greater level of observer coverage in the appropriate areas may provide the Council with a higher level of confidence in the assessment of any bycatch occurring in the designated areas as a basis for future management actions as necessary. Trawl sweep modifications have been effective in reducing unobserved bycatch mortality of Tanner crab in the Bering Sea, and similar effects may be realized in the Gulf of Alaska if modified trawl sweeps are employed in those groundfish fisheries.

7.7 Legal basis for the proposed action

NMFS manages the U.S. groundfish fisheries of the BSAI under the Fishery Management Plan (FMP) for this area. The Council prepared the FMP under the authority of the Magnuson-Stevens Act, and regulations implement the FMPs at 50 CFR part 679. General regulations that also pertain to U.S. fisheries appear at subpart H of 50 CFR part 600.

7.8 Number and description of small entities directly regulated by the proposed action

This action could directly regulate all trawl and pot vessels participating in Federal groundfish fisheries around Kodiak Island in the Central Gulf of Alaska. From 2003 through 2009, there were 68 nonpelagic trawl vessels, 47 pelagic trawl vessels, and 100 pot vessels with reported Tanner crab PSC, participating in one or multiple years in the groundfish fisheries in reporting area 630.

Fishing vessels, both catcher vessels and catcher/processors, are considered small, for RFA purposes, if their gross receipts, from all their economic activities combined, as well as those of any and all their affiliates anywhere in the world, (including fishing in federally managed non-groundfish fisheries, and in Alaska-managed fisheries), are less than or equal to \$4.0 million annually. Further, fishing vessels were considered to be large if they were affiliated with an AFA or Amendment 80 fishing cooperative, as the members of these cooperatives had combined revenues that exceeded the \$4.0 million threshold. Of the vessels with reported Tanner crab PSC, fishing in reporting area 630 from 2003 through 2009, 26 nonpelagic trawl vessels, 12 pelagic trawl vessels, and 97 pot vessels are considered small for RFA purposes.

7.8.1 Impacts of the action on small entities

Small entities that participate in the GOA nonpelagic trawl and pot fisheries will be affected by the area closures created by this action to the extent that those entities fish in the areas, and have to relocate elsewhere or obtain observer coverage in order to continue fishing in the closed areas. Operational costs could arise from changing the location of fishing or from observer costs. These effects are described in greater detail in Section 6.6.

Observer costs will increase for nonpelagic trawl and pot vessels, based on the number of days spent fishing inside the closed areas. Observer coverage in these areas will be separate from, and not count towards, meeting a vessel's overall 30 percent observer coverage requirement. The analysis (Section 6.6) estimates that the average annual cost per vessel has the potential to be \$2,086 for pot vessels between 60 feet and 125 feet LOA, \$2,814 for pot vessels less than 60 feet LOA, \$17,465 for nonpelagic trawl vessels that are between 60 feet and 125 feet LOA^{9,10}. The Council determined that the increased costs arising from these changes were necessary to protect Tanner crab.

⁹ This is a rough estimate based on the number of vessels that fished in the four proposed closure areas in 2009, and the average number of days they fished.

Observer costs associated with this action will only be in effect until the proposed observer restructuring program is implemented. At that time, the regulations from the restructured observer program will supersede observer requirements in this action. The restructured observer program would impose a 1.25 percent fee on the exvessel value of all groundfish landings in federally managed and parallel groundfish fisheries.

7.9 Recordkeeping and reporting requirements

The IRFA should include “a description of the projected reporting, recordkeeping, and other compliance requirements of the proposed rule, including an estimate of the classes of small entities that will be subject to the requirement and the type of professional skills necessary for preparation of the report or record...”

Implementation of the proposed action would not change the overall reporting structure and record keeping requirements of the vessels participating in the Bering Sea flatfish fisheries.

7.10 Federal rules that may duplicate, overlap, or conflict with proposed action

An IRFA should include “An identification, to the extent practicable, of all relevant Federal rules that may duplicate, overlap or conflict with the proposed rule...”

There do not appear to be any Federal rules that duplicate, overlap, or conflict with the proposed action.

7.11 Description of significant alternatives

An IRFA should include “A description of any significant alternatives to the proposed rule that accomplish the stated objectives of the Magnuson-Stevens Act and any other applicable statutes and that would minimize any significant (implicitly adverse) economic impact of the proposed rule on small entities.”

During consideration of this action, the Council evaluated a number of alternatives to the preferred alternative, including: (1) no action; (2) four permanent or seasonal area closures in which trawl or pot fishing would be prohibited; (3) four area closures in which trawl and pot fishing would only be allowed with increased observer coverage; (4) an exemption to the closures for vessels using pelagic trawl gear; and (5) an exemption to the closures for vessels using approved modified gear. None of these alternatives both met the objectives of the action and had a smaller adverse economic impact on small entities.

To take no action would not have met the Council’s objectives for this action, and would have continued a state in which no specific conservation measures exist in the GOA to address adverse interactions with Tanner crab by trawl and pot sectors targeting groundfish.

¹⁰ Note, this estimate is for observer coverage in all four proposed areas; the Council’s Preferred Alternative does not close statistical area 525630, and observer coverage is moot for nonpelagic trawl vessels in the Marmot area (statistical area 525807), as this area is permanently closed to nonpelagic trawling. These estimates are therefore believed to overstate the costs.

8 FMP and Magnuson-Stevens Act Considerations

8.1 Magnuson-Stevens Act National Standards

Below are the 10 National Standards as contained in the Magnuson-Stevens Act, and a brief discussion of the consistency of the proposed alternatives with those National Standards, where applicable.

National Standard 1 — Conservation and management measures shall prevent overfishing while achieving, on a continuing basis, the optimum yield from each fishery

The proposed action would impose area closures on some or all gear types participating in the Federal groundfish fisheries off Kodiak Island in the Central Gulf of Alaska. Target groundfish species that are currently caught in these areas include flatfish, Pacific cod, pollock, rockfish, and sablefish. It is not anticipated that the imposition of area closures will prevent the fishery from achieving annual total allowable catch for these species. These species are not currently in danger of overfishing and are considered stable. Additionally, the proposed action may reduce the mortality of *C. bairdi* crab species. While these are not subject to a Federal fishery managed under the Magnuson-Stevens Act, a reduction in PSC mortality of crab species may result in an increase in yield from the directed fishery. In terms of achieving “optimum yield” from a fishery, the Act defines “optimum”, with respect to yield from the fishery, as the amount of fish which—

- (A) will provide the greatest overall benefit to the Nation, particularly with respect to food production and recreational opportunities, and taking into account the protection of marine ecosystems;
- (B) is prescribed as such on the basis of the maximum sustainable yield from the fishery, as reduced by any relevant economic, social, or ecological factor; and
- (C) in the case of an overfished fishery, provides for rebuilding to a level consistent with producing the maximum sustainable yield in such fishery.

Overall benefits to the Nation may be affected by the proposed action, though our ability to quantify those effects are quite limited. Overall net benefits to the Nation would not be expected to change to an identifiable degree between the alternatives under consideration.

National Standard 2 — Conservation and management measures shall be based upon the best scientific information available.

Information in this analysis represents the most current, comprehensive set of information available to the Council, recognizing that some information (such as operational costs) is unavailable. Information previously developed on the GOA groundfish fisheries, as well as the most recent information available, has been incorporated into this analysis. It represents the best scientific information available.

National Standard 3 — To the extent practicable, an individual stock of fish shall be managed as a unit throughout its range, and interrelated stocks of fish shall be managed as a unit or in close coordination.

The annual TACs are set for GOA groundfish according to the Council and NMFS’s harvest specification process. NMFS conducts the stock assessments for these species and makes allowable biological catch recommendations to the Council. The Council sets the TAC for these species based on the most recent stock assessment and survey information. These GOA stocks will continue to be managed as a single stock under the alternatives in this analysis.

National Standard 4 — Conservation and management measures shall not discriminate between residents of different states. If it becomes necessary to allocate or assign fishing privileges among various U.S. fishermen, such allocation shall be (A) fair and equitable to all such fishermen, (B) reasonably calculated to promote conservation, and (C) carried out in such a manner that no particular individual, corporation, or other entity acquires an excessive share of such privileges.

Nothing in the alternatives considers residency as a criterion for the Council's decision. Residents of various states, including Alaska and states of the Pacific Northwest, participate in the major sectors affected by these allocations. No discriminations are made among fishermen based on residency or any other criteria.

National Standard 5 — Conservation and management measures shall, where practicable, consider efficiency in the utilization of fishery resources, except that no such measure shall have economic allocation as its sole purpose.

The wording of this standard was changed in the recent Magnuson-Stevens Act authorization, to consider rather than promote efficiency. Efficiency in the context of this change refers to economic efficiency, and the reason for the change, essentially, is to de-emphasize to some degree the importance of economics relative to other considerations (Senate Report of the Committee on Commerce, Science, and Transportation on S. 39, the Sustainable Fisheries Act, 1996). The analysis presents information relative to these perspectives and provides information on the economic risks associated with the proposed area closures.

National Standard 6 — Conservation and management measures shall take into account and allow for variations among, and contingencies in, fisheries, fishery resources, and catches.

All of the alternatives under consideration in the proposed action appear to be consistent with this standard.

National Standard 7 — Conservation and management measures shall, where practicable, minimize costs and avoid unnecessary duplication.

All of the alternatives under consideration appear to be consistent with this standard.

National Standard 8 — Conservation and management measures shall, consistent with the conservation requirements of this Act (including the prevention of overfishing and rebuilding of overfished stocks), take into account the importance of fishery resources to fishing communities in order to (A) provide for the sustained participation of such communities, and (B) to the extent practicable, minimize adverse economic impacts on such communities.

Many of the coastal communities in Alaska and the Pacific Northwest participate in the GOA groundfish fisheries in one way or another such as homeport to participating vessels, the location of processing activities, the location of support businesses, the home of employees in the various sectors, or as the base of ownership or operations of various participating entities. A summary of the level of fishery engagement and dependence in the communities of vessels affected by the proposed action is provided in the RIR.

An analysis of the alternatives suggests that while impacts may be noticeable at the individual operation level for at least a few vessels, the impacts at the community level for any of the involved fishing communities would be well under the level of significance. The sustained participation of these fishing communities is not put at risk by any of the alternatives being considered. Economic impacts to

participating communities would not likely be noticeable at the community level, so consideration of efforts directed at a further minimization of adverse economic impacts to any given community is not relevant.

National Standard 9 — Conservation and management measures shall, to the extent practicable, (A) minimize PSC, and (B) to the extent PSC cannot be avoided, minimize the mortality of such PSC.

The proposed action is specifically intended to reduce PSC and PSC mortality and injury of *C. bairdi* crab in the groundfish fisheries. The practicability of PSC reduction is discussed in the analysis of the impacts of the various alternatives and options, in Section 6.5.4 of the RIR.

National Standard 10 — Conservation and management measures shall, to the extent practicable, promote the safety of human life at sea.

The alternatives under consideration appear to be consistent with this standard. None of the alternatives or options proposed to modify the fishing grounds or gear of the flatfish fleet would change safety requirements for fishing vessels.

8.2 Section 303(a)(9) – Fisheries Impact Statement

Section 303(a)(9) of the Magnuson-Stevens Act requires that any plan or amendment include a fishery impact statement which shall assess and describe the likely effects, if any, of the conservation and management measures on (a) participants in the fisheries and fishing communities affected by the plan or amendment; and (b) participants in the fisheries conducted in adjacent areas under the authority of another Council, after consultation with such Council and representatives of those participants taking into account potential impacts on the participants in the fisheries, as well as participants in adjacent fisheries.

The alternative actions considered in this analysis are described in Section 2. The impacts of these actions on participants in the fisheries and fishing communities are the topic of Sections 6 and 7, in the RIR and IRFA.

Fishery Participants

The proposed actions directly impact participants in the GOA groundfish fisheries occurring around Kodiak Island in the Central GOA. The primary target fisheries that are prosecuted around Kodiak Island in the areas proposed for closure are flatfish (arrowtooth flounder, flathead sole, shallow-water flatfish, and rex sole), Pacific cod, pollock, rockfish, and sablefish. From 2001 through 2009, there have been a total of 536 different vessels participating in these directed fisheries.

Fishing Communities

The fishing communities that are expected to be potentially directly impacted by the proposed action are those communities which serve as homeports to the vessels potentially affected by the area closures, where they offload product, take on supplies, provide vessel maintenance and repair services, and provide homes to vessel owners and crew. Information on the residence of the vessel crew and processing crew that work aboard the potentially affected vessels is not readily available; however, generally companies operating vessels in the Central GOA groundfish sector tend to recruit crew from many locations.

Detailed information on the range of fishing communities relevant to the proposed action may be found in a number of other documents, including the *Alaska Groundfish Fisheries Final Programmatic Supplemental EIS* (NMFS 2004), *Sector and Regional Profiles of the North Pacific Groundfish Fishery*

(Northern Economics and EDAW 2001), and in a technical paper (Downs 2003) supporting the *Final EIS for Essential Fish Habitat Identification and Conservation in Alaska* (NMFS 2005) as well as that EIS itself. These sources also include specific characterizations of the degree of individual community and regional engagement in, and dependency upon, the North Pacific groundfish fishery.

Participants in Fisheries in Adjacent Areas

Neither the proposed action nor alternatives considered would significantly affect participants in the fisheries conducted in adjacent areas under the authority of another Council.

8.3 GOA FMP — groundfish management policy priorities

The alternatives discussed in this action accord with the management policy of the GOA Groundfish FMP. The Council's management policy (NPFMC 2009) includes the following objectives:

- Control the PSC of prohibited species through PSC limits or other appropriate measures.
- Continue and improve current incidental catch and PSC management program.
- Continue to manage incidental catch and PSC through seasonal distribution of total allowable catch and geographical gear restrictions.
- Continue program to reduce discards by developing management measures that encourage the use of gear and fishing techniques that reduce PSC which includes economic discards.

By proposing area closures or gear modifications to reduce PSC of *C. bairdi* crab, the Council is consistent with its management policy.

9 Analysis Summary

One of the purposes of an environmental assessment is to provide the evidence and analysis necessary to decide whether an agency must prepare an environmental impact statement (EIS). The analysis in this EA/RIR/IRFA is provided for public information and comment and does not constitute the final agency finding. The Finding of No Significant Impact (FONSI) is the decision maker's determination that the action will not result in significant impacts to the human environment, and therefore, further analysis in an EIS is not needed. The Council on Environmental Quality regulations at 40 CFR 1508.27 state that the significance of an action should be analyzed both in terms of "context" and "intensity." An action must be evaluated at different spatial scales and settings to determine the context of the action. Intensity is evaluated with respect to the nature of impacts and the resources or environmental components affected by the action. NOAA Administrative Order (NAO) 216-6 provides guidance on the National Environmental Policy Act (NEPA) specifically to line agencies within NOAA. It specifies the definition of significance in the fishery management context by listing criteria that should be used to test the significance of fishery management actions (NAO 216-6 §§ 6.01 and 6.02). These factors form the basis of the analysis presented in this EA/RIR/IRFA. The results of that analysis are summarized here for those criteria.

Context: For this action, the setting is the Central GOA groundfish fisheries that participate in specific areas around Kodiak Island that are proposed for closure. Any effects of this action are limited to this area, or adjacent areas in the Central GOA where vessels may choose to catch their target fish once they have been closed out of specific fishing grounds. The effects of this action on society within this area are on individuals directly and indirectly participating in these fisheries and on those who use the ocean resources. Because this action concerns the use of a present and future resource, this action may have impacts on society as a whole or regionally.

Intensity: Considerations to determine intensity of the impacts are set forth in 40 CFR 1508.27(b) and in the NAO 216-6, Section 6. Each consideration is addressed below in order as it appears in the NMFS Instruction 30-124-1 dated July 22, 2005, Guidelines for Preparation of a FONSI. The sections of the EA that address the considerations are identified.

1) *Can the proposed action reasonably be expected to jeopardize the sustainability of any target species that may be affected by the action?*

(EA Sections 4.2 and 4.5). No. No significant impacts, either adverse or beneficial, on target species were identified for Alternatives 2 or 3. No changes in overall amount or timing of harvest of target species are expected with any of the alternatives or options in the proposed action, and the general location of harvest is also likely to be similar to the status quo, although there may be localized shifts. Therefore, no impacts on the sustainability of any target species are expected.

2) *Can the proposed action reasonably be expected to jeopardize the sustainability of any non-target species?*

(EA Sections 4.1 and 4.2). No. Potential effects of Alternatives 2 and 3 on non-target and prohibited species are expected to be insignificant and similar to status quo because no overall harvest changes to target species were expected. Some benefit to *C. bairdi* crab, a prohibited species caught as PSC in the groundfish fisheries, may accrue due to the area closures. Because no overall changes in target species harvests under the alternatives is expected, the alternatives and option are not likely to jeopardize the sustainability of any nontarget/prohibited species.

- 3) *Can the proposed action reasonably be expected to cause substantial damage to the ocean and coastal habitats and/or essential fish habitat as defined under the Magnuson-Stevens Act and identified in the fishery management plans (FMPs)?*

(EA Section 4.4). No. No significant impacts, either adverse or beneficial, were identified for Alternatives 2 or 3 on ocean or coastal habitats or EFH. The alternatives provide additional protection to areas around Kodiak Island where area closures are proposed. Alternative 3 is less protective of habitat than Alternative 2 because it allows an exemption to the area closures for vessels that meet a 100 percent observer coverage requirement. Substantial damage to ocean or coastal habitat or EFH by Alternatives 2 or 3 is not expected.

- 4) *Can the proposed action be reasonably expected to have a substantial adverse impact on public health or safety?*

(EA Chapter 1). No. Public health and safety will not be affected in any way not evaluated under previous actions or disproportionately as a result of the proposed action. The proposed action for Alternatives 2 and 3 will not change fishing methods (including gear types), timing of fishing, or quota assignments to gear groups, which are based on previously established seasons and allocation formulas in regulations.

- 5) *Can the proposed action reasonably be expected to adversely affect endangered or threatened species, marine mammals, or critical habitat of these species?*

(EA Section 4.3). No. Alternatives 2 and 3 would create area closures around Kodiak Island in the Central GOA. The proposed action would not change the Steller sea lion protection measures, ensuring the action is not likely to result in adverse effects not already considered under previous ESA consultations for Steller sea lions and their critical habitat. The area adjacent to these closures, into which the groundfish vessels may be displaced, is not identified as critical habitat for any ESA-listed species and population level effects are not expected. Because there will be no change in overall harvest or fishing methods, the alternatives are not likely to adversely affect ESA-listed species or their designated critical habitat.

- 6) *Can the proposed action be expected to have a substantial impact on biodiversity and/or ecosystem function within the affected area (e.g., benthic productivity, predator-prey relationships, etc.)?*

(EA Section 4.5). No significant impacts, either adverse or beneficial, on biodiversity, ecosystem function, marine mammals, or seabirds were identified for Alternatives 2 or 3. The alternatives would provide protection to biodiversity and ecosystem function by creating area closures around Kodiak Island, and likely benefit marine features that provide an ecosystem function.

- 7) *Are significant social or economic impacts interrelated with natural or physical environmental effects?*

(EA/RIR/IRFA Chapters 4, 6, and 7). Socioeconomic impacts of this action result from displacement of vessels that fish in the proposed area closures, or additional costs associated with the options that would allow them to be exempted from the closures. The social or economic impacts of the alternatives are not expected to be significant as target fish are harvested in areas adjacent to the proposed closure areas, and meeting the requirements for the exemptions do not appear to be excessively expensive to the groundfish fleet and no other changes to fishing patterns or practices will result from this action. Beneficial social impacts are likely for those who depend on directed fisheries for *C. bairdi* crab, a resource that may be protected by this action. No significant impacts, either adverse or beneficial, were identified for Alternatives 2 or 3 for social or economic impacts interrelated with natural or physical environmental effects.

8) *Are the effects on the quality of the human environment likely to be highly controversial?*

(EA Chapters 4 and 6). No. This action is limited to specific areas around Kodiak Island in the Central GOA, areas that are historically of value to the groundfish fleet. Development of the proposed action has involved participants in field testing from the scientific and fishing communities and the results were presented through Council and other public meetings and the potential impacts on the human environment are well understood. No issues of controversy were identified in the process.

9) *Can the proposed action reasonably be expected to result in substantial impacts to unique areas, such as historic or cultural resources, park land, prime farmlands, wetlands, wild and scenic rivers or ecologically critical areas?*

(EA Chapter 4). No. This action would not affect any categories of areas on shore. This action takes place in Federal waters in the geographic area of the Central GOA three miles offshore. The land adjacent to this marine area may contain archeological sites of native villages. This action would occur in adjacent Federal marine waters so no impacts on these cultural sites are expected. The marine waters where the fisheries occur contain ecologically critical areas. Effects on the unique characteristics of these areas are not anticipated to occur with this action because of the amount of fish removed by vessels are within the total allowable catch (TAC) specified harvest levels and the alternatives provide protection to EFH and ecologically critical nearshore areas.

10) *Are the effects on the human environment likely to be highly uncertain or involve unique or unknown risks?*

No. The potential effects of the action are well understood because of the fish species, harvest methods involved, and area of the activity. For marine mammals and seabirds, enough research has been conducted to know about the animals' abundance, distribution, and feeding behavior to determine that this action is not likely to result in population effects (EA Section 4.3). The potential impacts of different gear types on habitat also are well understood, as described in the EFH EIS (NMFS 2005) (EA Section 4.4).

11) *Is the proposed action related to other actions with individually insignificant, but cumulatively significant impacts?*

(EA Section 4.6). No. Beyond the cumulative impact analyses in the 2006 and 2007 harvest specifications EA and the Groundfish Harvest Specifications EIS, no other additional past or present cumulative impact issues were identified. The combination of effects from the cumulative effects and this proposed action are not expected to result in significant impacts, either adverse or beneficial, for any of the environmental component analyzed.

12) *Is the proposed action likely to adversely affect districts, sites, highways, structures, or objects listed in or eligible for listing in the National Register of Historic Places or may cause loss or destruction of significant scientific, cultural, or historical resources?*

(EA Chapter 4). No. This action will have no effect on districts, sites, highways, structures, or objects listed or eligible for listing in the National Register of Historic Places, nor cause loss or destruction of significant scientific, cultural, or historical resources. Any shipwrecks that may occur where fishing activity occurs are not likely to be disturbed, as these sites are identified on nautical charts and avoided by fishers to protect their gear. This proposed action is not likely to change this behavior and therefore is not likely to impact shipwreck sites. Besides shipwrecks, there are no records of other historical sites present in the proposed action area.

13) *Can the proposed action reasonably be expected to result in the introduction or spread of a nonindigenous species?*

(EA Chapter 4). No. This action poses no effect on the introduction or spread of nonindigenous species into the Gulf of Alaska beyond those previously identified because it does not change fishing, processing, or shipping practices that may lead to the introduction of nonindigenous species.

14) *Is the proposed action likely to establish a precedent for future actions with significant effects or represent a decision in principle about a future consideration?*

No. This action would provide for additional protection to GOA *C. bairdi* crab by imposing area closures. This action does not establish a precedent for future action because area closures have been frequently used as a management tool for the protection of marine resources in the Alaska groundfish fisheries. Pursuant to NEPA, for all future actions, appropriate environmental analysis documents will be prepared to inform the decision makers of potential impacts to the human environment and to implement mitigation measures to avoid significant adverse impacts.

15) *Can the proposed action reasonably be expected to threaten a violation of federal, state, or local law or requirements imposed for the protection of the environment?*

No. This action poses no known violation of federal, state, or local laws or requirements for the protection of the environment.

16) *Can the proposed action reasonably be expected to result in cumulative adverse effects that could have a substantial effect on the target species or non-target species?*

(EA Sections 4.2 and 4.6). No. The effects on target and non-target species from the alternatives are not significantly adverse as the overall harvest of these species will not be affected. No cumulative effects were identified that added to the direct and indirect effects on target and nontarget species would result in significant impacts, either adverse or beneficial.

10 Preparers and Agencies and Persons Consulted

10.1 Preparers

Diana Evans, NPFMC
Sally Bibb, NMFS Alaska Region
Mike Fey, AKFIN
Sarah Gaichas, NMFS AFSC
Jon McCracken, NPFMC
John Olson, NMFS Alaska Region
Dr. Craig Rose, NMFS AFSC

Color Figure 8 Observed *C. bairdi* Tanner crab PSC in the pelagic trawl groundfish fishery, summed over 2001 through 2009¹¹

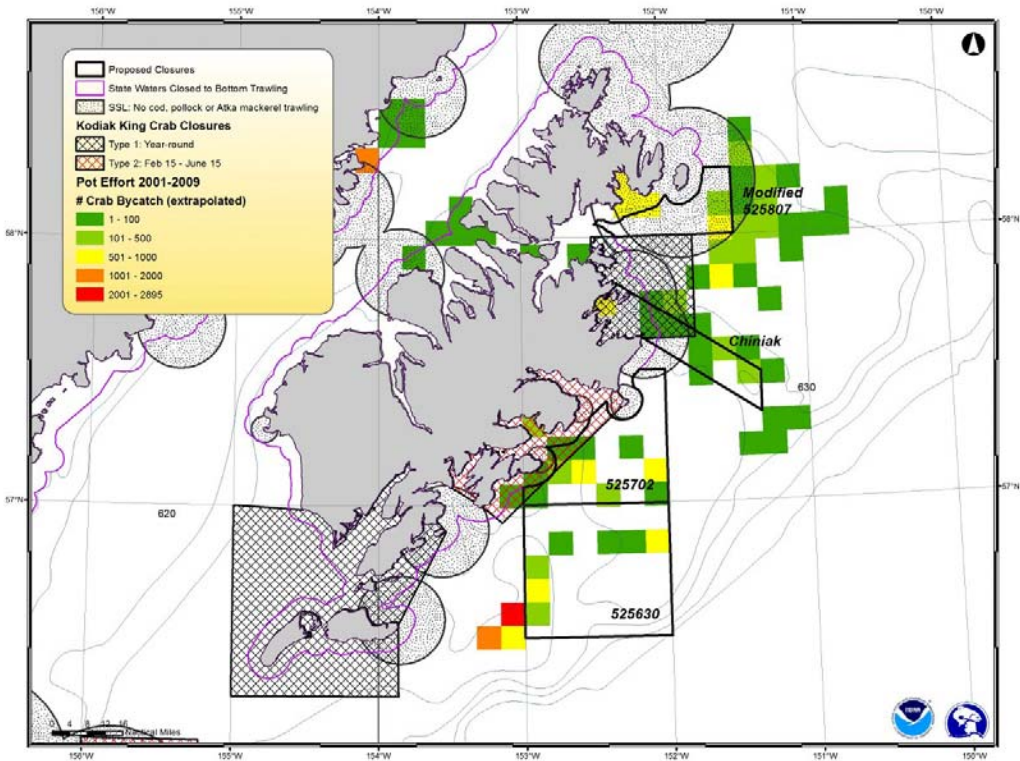

¹¹ There is an important limitation in the observer program data for PSC from the shoreside pollock fishery when it is used for spatial analysis. The limitation is due to a technical database problem, which was corrected by NMFS re-design of the observer database implemented in 2008. The issue is that PSC in the shoreside pollock fishery are sampled at the plant, rather than onboard the vessel. This is because of the particular handling of large volumes of catch in the pollock fishery. Typically, catch is rapidly placed in below deck refrigerated seawater tanks and there is limited opportunity to take large samples. As all hauls are mixed together in the vessel's hold, the entire delivery is monitored for PSC at the shoreside plant upon delivery. Prior to 2008 the Observer Program database did not provide for capturing the delivery level information. Instead, the delivery level was proportioned back to individual tows made during the trip. This was done to fit the data into the existing system. We caution that care must be exercised when attempting to interpret PSC rates at the haul level. The spatial distribution currently displayed in the document maps the PSC data by individual tows. In effect, this averages the PSC among several hauls at several locations, when in fact it could possibly be the case that all the PSC was caught during one haul in one location, and other locations had little or no associated PSC.
