## BSA Plan Team report

Grant Thompson, chair
Diana Stram, coordinator

December 5, 2018

## Team members

- Grant Thompson, chair (AFSC REFM)
- Diana Stram, coordinator (NPFMC)
- Steve Barbeaux (AFSC REFM)
- Mary Furuness (NMFS AKRO)
- Alan Haynie (AFSC REFM)
- Alan Hicks (IPHC)
- Lisa Hillier (MDFW)
- Kirstin Holsman (AFSC REFM)
- Andy Kingham (AFSC FMA, unofficial)
- Brenda Norcross (UAF)
- Kalei Shotvell (AFSC ABL)
- Chris Siddon (ADF\&G)
- Jane Sullivan (ADF\&G)
- Cindy Tribuzio (AFSC ABL)

+95\% from 2017 (289K mt)

## Pacific cod distribution by catch weight

## SEBS Pacific cod

## NEBS Pacific cod

## SEBS \& NEBS Yellowfin sole

SEBS Biomass 1.9 mmt
-32\% from 2017 (2.8 mmt)

NEBS Biomass
373K mt
+1\% from 2017 (368K mt)

## SEBS \& NEBS Northern rock sole

## Chapter summaries

## Chapter 1: EBS walleye pollock (full)

- Suitch to author's presentation (Team comments will follow)

## EBS walleye pollock, continued

- Tier 1a but authors recommend setting ABC at the Tier Za level, consistent w/ past SSC practice
- See "risk table" in chapter (concern level 2)
- Discussion (no consensus) on tier system and the risk table:
- Is this really a Tier 1 assessment?
- Should a "tier concerns" column be added to the risk table?
- Should the "assessment" and "pop dy" concern levels be higher?
- Concerns about the tier system in general

## EBS walleye pollock, continued

## Total (age 0+) biomass, EBS Pcod

U.S. Department of Commerce | National Oceanic and Atmospheric Administration | NOAA Fisheries | Page 44 This information is distributed solely for the purpose of pre-dissemination peer review under applicable information quality guidelines. It has not been formally disseminated by the National Marine Fisheries Service and should not be construed to represent any agency determination or policy.

## Choice of final model, EBS Pcod

## Criteria and choice of final model

The following criteria were used to choose the final model:

- Are catchability estimates plausible?
- Is retrospective performance acceptable?
- Are changes in the complexity of model structure justified?
- Are changes in model structure appropriately incremental?

Evaluation of the eight models with respect to the above criteria resulted in a choice of Model 16.6i as the final model

## Final recommendations

## Author's reasons for not setting $A B C<\max A B C$

SSC guidance

- Last year, when the SSC concluded that no reduction was warranted:
- Combined EBS+NBS survey biomass was down 5\%
- Persistence of NBS biomass was unknown
- Genetic relationship between EBS and NBS fish was unknown
- This year:
- Combined EBS+NBS survey biomass is up 15\%
- Persistence of NBS biomass has been corroborated
- EBS and NBS fish have been shown to be genetically similar

2019 maxABC is already down significantly from 2018 ABC (-10\%)

- With an even bigger drop from 2019 to 2020 (-24\%)

## Reasons for not setting $A B C<m a x A B C$ (2 of 2)

- Difficulty in navigating the new rules
- How to map risk matrix "concerns" into reductions vithout violating new prohibition against including socioeconomic concerns in ABC?
- If it is just a matter of adjusting ABC to account for a retrospective bias, this might not be too hard, but M16.6i's retrospective bias is low
- What is gained/lost by various reductions, and how to choose an objective that does not involve socioeconomic concerns?

## EBS Pacific cod, Team Discussion

- The Team discussed the NBS survey results, what they imply about the population, and how it should be used in the assessment model, leading to identification of three hypotheses:

1. Pacific cod in the NBS are insignificant to the stock and should not be considered in management
2. Pacific cod have the capability to migrate from the EBS to the NBS each year, and the stock extends over these two areas
3. The population in the EBS and the NBS may simply be a mixture of the same stock, or the fish in these two areas are subpopulations of the same stock vith different life-history characteristics

- More observations (e.g., genetic studies, tagging) are needed to reject any of these hypotheses

## EBS Pacific cod, continued

- If Pacific cod are undertaking an annual migration, that migration may occur at the same time as the survey, and there is a possibility that the survey is double-counting some fish, making catchability greater than 1
- Catchability could be affected by the truncated area surveyed in 2018
- Pacific cod were observed by other surveys outside of the truncated area in 2018, and a bias in the 2018 estimate may be present
- Furthermore, NBS surveys were conducted in only three years, and if a single summed index is considered in the assessment model, this implies that years without NBS survey estimates have zero biomass in that area
- Models with time-varying catchability may have captured some of these concerns, but a spatial analysis of the survey data with temporal and spatial correlation may provide a useful index

## EBS Pacific cod, continued

- Investigating fishery CPUE data throughout the year at specific locations may help understand migration patterns and the intersection of a migrating population with the survey
- The longline fleet has recently started fishing on the population in the NBS, which suggests that the population has expanded in the NBS
- There is a sense that the fishery follows the fish northward, but the break between A and B seasons makes it difficult to tell
- Industry participants reported that when they arrive on the grounds in the north for B-season, the fish are already there
- Industry participants reported that they also follow fish south at the end of the season
- Additionally, connections may occur with GOA (e.g., Unimak Pass), but the implications of these connections are unknown

## EBS Pacific cod, continued

- Models 16.6, 16.6i, 16.6j, and 16.6k capture the three hypotheses:
- Model 16.6 is a strong bookend and assumes either that the fish in the NBS are insignificant to management of the stock, or that the fish in that area are unlikely to contribute reproductively to the population
- e.g., they could die if the climate quickly shifted back to cold years with quick formation of ice or were harvested in Russian waters
- Model 16.6i assumes that the fish in the NBS and EBS are all from the same population and should be modeled as one, with no fish in the NBS in years without a NBS survey
- Model 16.6j incorporates time-varying catchability that may compensate for assuming zero NBS fish in years with no survey
- Model 16.6 k models the observations in the two areas separately but as a single population

## EBS Pacific cod, continued

- After considering many options for a management model, including averaging various models, the Team recommended that Model 16.6i be used for management because it is the author recommended model and the author clearly itemized the justifications for selecting this model as the preferred model
- In particular, the Team noted:
- Model 16.6 i is an incremental change that includes the NBS survey data without introducing too much complexity
- While all of the models exhibit positive retrospective bias, Model 16.6i had the lowest retrospective bias of the models presented
- Model 16.6i satisfies many SSC requests
- Although the Team accepted Model 16.6i, other models, such as 16.6j and 16.6 k, may more appropriately handle years where there are no survey data from the NBS as well as capture changes in distribution

## EBS Pacific cod, continued

- Moreover, the Team identified the following concerns with Model 16.6i:
- Years without an NBS survey implicitly assume that the biomass in the NBS was zero, which may result in a conservative view of the decline in recent years (e.g., 2014-2018) of the survey index
- Larger fish were observed in the NBS, but the composition data were simply summed, which may not accurately reflect selectivity of the combined survey
- This simple summation of the survey abundances assumes a survey of a population at a particular moment in time, but the timing of the north-south migration is not completely understood, and the survey may be following and interacting with migrating fish, possibly resulting in double-counting and a bias at the EBS/NBS boundary
- (continued on the next slide)

## EBS Pacific cod, continued

- Concerns with Model 16.6i (continued):
- The EBS and NBS survey observations are based on slightly different grids and occur in slightly different time periods and therefore may have different selectivity patterns and availability, warranting the separate treatment of the two indices
- Although the summed EBS-NBS biomass index has remained somewhat constant over the last 5 years, this may reflect a bias resulting from the larger fish in the NBS agecomps relative to EBS
- It is uncertain if the fish in the NBS will contribute to current and future spawning biomass
- Given the unprecedented shift in distribution and uncertain future climate conditions, there could be additional natural mortality in the NBS that is not accounted for in the present model

## EBS Pacific cod, continued

- Alternative to a single model, the Team discussed and seriously considered averaging some or all of the 16.x models to characterize structural uncertainty related to the three hypotheses stated earlier
- In the end, the Team did not average models, largely because:
- Additional work would be needed to clean up major concerns with all models (of which 16.6i had the fewest):
- strong retrospective patterns
- use of options not common for surveys (time-varying catchability)
- omission of observations (NBS survey)
- Model 16.6i was the most parsimonious and satisfied the principle of Occam's Razor
- (continued on next slide)

## EBS Pacific cod, continued

- Reasons why the Team did not average models (continued):
- After much discussion (until 6:30 pm Wednesday), Model 16.6i was the model that the Team felt most comfortable with
- The Team made the rounds attempting to justify each model and always came back to Model 16.6i
- The author did not put forward any support for an ensemble
- The Team did not have time to adequately discuss, choose, and defend an ensemble
- The Team discussed this again on Friday afternoon per the schedule adopted Wednesday evening upon adjourning, revisiting minutes to confirm the notes
- With additional time, the Team might have revisited the decision not to create an ensemble

## EBS Pacific cod risk table

| Assessment-related | Population dynamics | Environmental/ ecosystem |
| :---: | :---: | :---: |
| Retrospective bias, age data potentially unreliable, wide range of results with different model assumptions, (B23\%-B49\%) uncertainty in stock structure. <br> Conclusion: Level 2-3, substantially increased concerns to major concerns | Recent low recruitment, including the lowest observed, strong decline in survey numbers, spatial distribution is unprecedented, with unknown consequences. Potential for increased natural mortality. <br> Conclusion: Level 2-3, substantially increased concerns to major concerns | Unprecedented lack of sea ice, and absent cold pool. Reduced primary and secondary production, forecasts of continued warm conditions, unprecedented extent and duration of bird die offs with indications of insufficient prey resources. <br> Conclusion: Level 2-3, substantially increased concerns to major concerns |

Overall score is Level 2-3: Author's recommended $\mathrm{ABC}=$ maxABC. Plan Team filled out risk table during meeting, and recommended 20\% reduction by referencing the historical distribution of percent reductions.

## A Pacific cod

- Survey biomass

## Al Pacific cod, continued

- Biomass apportionment
- "Harvest limit" for the WAI is computed by subtracting State GHL from $A \mathrm{I}$ ABC, then multiplying by proportion of biomass in WAI
- Proportion "determined by the annual stock assessment process"
- Based on 2019 estimate from RE model, proportion = 15.7\%
- Down from 25.6\% estimated in 2016-2017 assessments
- GHL has been 27\% of ABC since 2016; increasing to 31\% in 2019
- Recommended 2019 ABC is 20,600 t, implying a 2019 WAI harvest limit of $20,600 t \times(1.00-0.31) \times 0.157=2,232 t$
- 2018 WAI catch through 11/24 $=2,694$ t
- (continued on next 3 slides)

## Al Pacific cod, continued

- Biomass apportionment, continued
- Team discussion:
- Options include basing the proportion on:
- the raw survey data or the RE model estimates
- the most recent estimate or an average over recent years
- Using the model-based estimate intrinsically introduces some level of smoothing compared to the survey observations
- Team ultimately agreed that $15.7 \%$ is the appropriate proportion

## Al Pacific cod, continued

- Following past practice, the value of $M$ used in the Tier 5 harvest control rule is borrowed from the EBS assessment, resulting in a change from 0.36 to 0.34 this year

## Chapter 3: sablefish (full)

- Covered in GOA Team presentation

## EBS Yellowfin sole

## Yellowfin sole, continued

- A: constant $Q$; B: temperature only, C: temp., start date, and interaction

## Yellowfin sole, continued

- Stock status and trend:
- 2003 and 2009 cohorts are 49\% and 21\% above average
- However, 9 of the last 12 cohorts are below average
- Spamning biomass has declined almost continuously since 2007
- 2019 spawning biomass is $68 \%$ of $B_{0}$ and $85 \%$ above $B_{M S Y}$

Authors' chose not to include the NBS survey data in a model despite the high abundance of yellowfin sole in that region

- The author did not think that the 2018 NBS survey was fully appropriate for this stock as it did not include shallow stations that would have been informative for yellowfin sole

## Yellowfin sole, continued

## Blackspotted/rougheye rockfish

## Blackspotted/rougheye, continued

Stock status and trend (Al only, based on Model 18.2):

- Following a string of 20 consecutive below-average cohorts, 19982011 cohorts are all above average
- Spawning biomass has increased steadily since 2007 (28\% by 2018)
- 2019 spawning biomass is $32 \%$ of $B_{100 \%}$
- The Team recommended that the results of Models 18.1 and 18.2 be averaged in order to arrive at the 2019 and 2020 harvest specs

## Blackspotted/rougheye, continued

- Team discussion (continued):
- Additionally, the utility of the MSSC as a guideline for fishery removals on a finer spatial scale was discussed
- Industry participants generally liked having the MSSC as a guideline to work toward
- Team opinion was mixed regarding subarea ABCs versus MSSCs
- Team to reconsider separate area-specific ABCs in September

| Year | WAI MSSC | WAI Catch | Catch/MSSC |
| ---: | ---: | ---: | ---: |
| 2015 | 46 | 67 | 1.46 |
| 2016 | 58 | 38 | 0.65 |
| 2017 | 29 | 34 | 1.17 |

## Chapter 16: other rockfish (full)

New data:

- 2018 Al survey biomass (down 14\% from 2016)

Model alternatives:

- Tier 5 random effects
- For non-SST species combined, EBS shelf survey yielded estimates of zero for both biomass and standard error in 12 of 37 years
Stock status and trend
- Model biomass generally increasing throughout time series

## What are Bering Sea and Aleutian Islands

 "Other Rockfish'- Most abundant:
- shortspine thornyhead; Sebastolobus alascanus,
- dusky rockfish; Sebastes variabilis,
- harlequin rockfish; Sebastes variegatus,
- redlbanded rockfish; Sebastes babcocki, redstriped rockfish; Sebastes proriger,
- yelloweye rockfish; Sebastes ruberrimus, and sharpchin rockfish; Sebastes zacentrus

24 species, including unidentified.

## Survey biomass estimates

Aleutian Is. non-SST

Aleutian Islands SST
E

- Other rockfish not increasing

Bering Sea shelf all Other Rockfish

Bering Sea slope non-SST Other Rockfish

Bering Sea slope SST

Combined Random effect estimates of all Other Rockfish biomass (BSAI)

## Other rockfish, continued

- Potential overharvest of non-SST species

- Exploitation rates > 1 are suspect
- However, survey estimates of non-SST species are highly imprecise

- Possible mixing with GOA?

## Other rockfish, continued

## Chapter 17: Atka mackerel (full)

- New data:
- 2017 fishery agecomp
- 2018 Al survey biomass (down 21\%)
- 1986 survey agecomp removed
- Model alternatives:
- Model 16.Ob: base model (introduced last year)
- Stock status and trend:
- 1998-2001 cohorts were all very strong, and the 2006 and 2007 cohorts are 56\% and 33\% above average
- Spawning biomass reached all-time high in 2005; decreasing since
- Overall decrease of 57\% through 2018
- 2019 spawning biomass is $38 \%$ of $B_{100 \%}$

Bottom trawl survey CPUE distributions of Atka mackerel catches

## Atka mackerel, continued

## Area apportionment:

- Authors conducted a thorough examination of the survey and fisheries data to determine if the survey decline reflects the stock
- Fishery data from the CAI inconsistent w/ survey

## Atka mackerel

## - Area apportionment

|  |  | 2019 |  |

## Chapter 18: skates (full)

- New data:
- A new time series of skate catches by species was created for this assessment (previewed in September/October)
- 2017 EBS shelf survey biomass
- down 3\% from 2016 (Alaska skate), up 79\% (other skates)
- 2018 EBS shelf survey biomass
- up 2\% from 2017 (Alaska skate), down 3\% (other skates)
- 2018 Al survey biomass
- up 50\% from 2016 (AK skate, minor part), up 3\% (other skates)
- 2017 and 2018 EBS shelf survey sizecomps (Alaska skate only)
- 2017 fishery sizecomps (Alaska skate only)

## Skates, continued

- Model alternatives:
- Alaska skate: Model 14.2 (base model)
- Other skates: Tier 5 random effects
- Stock status and trend:
- Alaska skate:
- 2003-2010 cohorts all above average, more recent all below
- Spawning biomass increased continuously from 2006-2018
- Currently at all-time high
- 2019 spawning biomass is $65 \%$ of $B_{100 \%}$
- Other skates:
- Survey biomass has been relatively flat or increasing, except Al whiteblotched and AI leopard (declining since 2006 and 2010)

## Alaska skate fit to survey

## "other skate" biomass - Aleutian Islands

## Skates, continued

| Alaska skate: | Quantity | Last asmt. | This asmt. | Change |
| :---: | :---: | :---: | :---: | :---: |
