PUBLIC REVIEW DRAFT

Environmental Assessment
for a Proposed Amendment to the Fishery Management Plan for the
Bering Sea And Aleutian Islands King And Tanner Crabs

Rebuilding Plan for Saint Matthew Island Blue King Crab

May 2020

Anchorage, AK 99501
(907) 271-2809

Abstract: This environmental assessment analyses an action to prepare and implement an
amendment to the BSAI Crab FMP to rebuild the Saint Matthew Island blue king crab
stock in compliance with section 304(e)(3) of the Magnuson-Stevens Act. A range of
alternative rebuilding time frames is considered based on whether or not directed fishing
is permitted during stock recovery. The impacts of the alternatives considered under the
action upon crab resources, fishery participants, habitat, and other components of the
human environment are discussed in the analysis.

Accessibility of this Document: Effort has been made to make this document accessible to individuals with
disabilities and compliant with Section 508 of the Rehabilitation Act. The complexity of this document may
make access difficult for some. If you encounter information that you cannot access or use, please call us at
907-271-2809 so that we may assist you.

Source: Ecosystem and Socioeconomic Profile of the Saint Matthew Blue King Crab stock in the Bering Sea 2019.
Executive Summary

Purpose and Need

The St. Matthew Island blue king crab (SMBKC) stock was declared overfished on October 22, 2018, because the estimated spawning biomass was below the minimum stock size threshold specified in the crab FMP. In order to comply with provisions of the Magnuson-Stevens Fishery Conservation and Management Act (MSA), a rebuilding plan must be implemented prior to the start of the 2020/2021 fishing season.

The SMBKC directed fishery has been closed since the 2016/2017 season. The St. Matthew Island Habitat Conservation Area (SMIHCA) was created in 2008 and expanded through Amendment 94 to the BSAI Groundfish FMP (NPFMC 2009) to protect blue king crab habitat; vessels fishing with non-pelagic trawl gear are prohibited from fishing in the SMIHCA. Other fishery closure areas include a 20 nm Steller sea lion closure around the southern tip of Hall Island (NMFS 2001) to trawling, hook-and-line, and pot fisheries for pollock, Pacific cod, and Atka mackerel. In addition, State jurisdictional waters (0 to 3 nm from shore) surrounding St. Matthew, Hall, and Pinnacle Islands are closed to the taking of king and Tanner crab and to commercial groundfish fishing.

This action is necessary to facilitate compliance with the requirements of the MSA to end and prevent overfishing, rebuild overfished stocks, and achieve optimum yield.

Alternatives

The Council established the following alternatives for analysis at its June 2019 meeting. Those alternatives were revised, and preliminary preferred alternatives were selected at the December 2019 meeting. The Council’s preliminary preferred alternatives are highlighted in **bold**.

Alternative 1: No Action: State harvest strategy with no rebuilding plan

Alternative 2: Set target rebuilding time frame for the number of years necessary to rebuild the stock to the BMSY level at a probability ≥50%. The stock will be considered “rebuilt” once it reaches BMSY.

   Option 1: No directed fishing until the stock is rebuilt

   Option 2: Allow the directed fishery to open based on the state harvest strategy while the stock is rebuilding

Updates from the Initial Review Draft (December 2019)

This document contains clarifications and improvements to the December 2019 initial review draft, notable changes include:

- Explanation of the difference between the basis for \( B_{MSY} \) and the basis for the biomass threshold used for opening the SMBKC fishery under the State of Alaska harvest strategy (Section 2.2)
- Clarification of Alternative 1 (no action) with regard to harvest constraints and future stock biomass (clarified in the wording of the alternative above and in Section 2.1)
- Description of bycatch monitoring during rebuilding originally described only in Section 2.3 now also included in Section 3.3.3.
- Figures added for projections that include recruitment estimates from the recent timeframe only (Section 3.3.1)
- Figure added illustrating uncertainty in the rebuilding projections (Section 3.3.6)
Environmental Assessment

Target Species

Based on the best available information on the biology of the SMBKC stock and environmental conditions, the time necessary to rebuild the stock will exceed 10 years. The SMBKC stock has been in a low productivity phase since 1996 and population recovery will be greatly influenced by environmental conditions. Despite existing protections and frequent fishery closures, the stock has remained in this low productivity phase. Projections of stock recovery incorporate ecosystem constraints on productivity by forecasting recruitment as a function of stock size in model-recruit parameters. The estimated time for rebuilding under the Council’s preliminary preferred alternative, taking into account the biology of the species and current environmental conditions, is 25.5 years.

Management measures to further reduce potential bycatch of SMBKC in the groundfish fisheries are not proposed as part of the Council’s rebuilding plan. In projections that apply average bycatch levels during rebuilding, the time for stock recovery was not differentiable from the “no bycatch” scenario. Additionally, the time for stock recovery was minimally affected in projections that used the maximum level of observed bycatch as a “worst case scenario” throughout rebuilding.

The contribution of the rebuilding plan to stock recovery would be additive to measures already in place that limit the effects of fishing activity on SMBKC. The directed fishery for SMBKC is managed under the State of Alaska harvest strategy and has been closed since the 2016/2017 season, prior to the stock being declared overfished. Measures to protect habitat and reduce bycatch potential include prohibitions on nonpelagic trawl gear in the St. Matthew Island Habitat Conservation Area (SMIHCA; NPFMC 2009). Additionally, a 20 nm Steller sea lion closure area around the southern tip of Hall Island (NMFS 2001) prohibits trawling, hook-and-line, and pot fisheries for pollock, Pacific cod, and Atka mackerel may help reduce SMBKC bycatch in those fisheries. Finally, State jurisdictional waters (0 to 3 nm from shore) surrounding St. Matthew, Hall, and Pinnacle Islands are closed to the taking of king and Tanner crab and to commercial groundfish fishing, further reducing the potential for SMBKC bycatch.

Communities

Consistent with MSA §304(e)(4)(A) provisions and MSA National Standard 1 guidance, the Council’s preliminary preferred alternative (Alternative 2 / Option 2) rebuilds the stock in as short a time as possible, while also taking into account the needs of fishing communities. Given that the fishery has been intermittently prosecuted due to the relatively low but highly variable biomass in recent years, some vessels could re-enter the fishery as rebuilding occurs and benefits to home communities as well as the processing sector in St. Paul, AK could be expected. The fishery was last open during the 2015/2016 season and there have been limited openings with relatively low Total Allowable Catch limits (TACs) over the last 20 years. For those reasons, vessel and community dependence on SMBKC is low compared to other BSAI crab fisheries but can be a significant source of revenue for these vessels and communities in years when the fishery is open. The Council’s preliminary preferred alternative which follows the State harvest strategy would allow for some directed fishing opportunity after the stock has grown to the point where an opening would be allowed, while rebuilding continues. The timeline for full rebuilding of the fishery and associated community benefits is expected to be protracted under current environmental conditions. Greater flexibility during rebuilding would be more responsive to the uncertainty facing crab fisheries and affected communities over the next two decades. Option 2 provides flexibility by allowing limited fishing after the stock has rebuilt to the threshold level necessary for an opening under the State harvest strategy.
1. Introduction

1.1. Purpose and Need

Pursuant to the Magnuson-Stevens Fishery Conservation and Management Act (MSA) section 304(e)(4)(A) and the National Standard Guidelines, the purpose of this proposed action is to develop a rebuilding plan to prevent overfishing and to rebuild the Saint Matthew Island blue king crab (SMBKC) stock. Rebuilding should take place in as short a time as possible, taking into account the status and biology of any overfished stocks of fish, the needs of fishing communities, recommendations by international organizations in which the United States participates, and the interaction of the overfished stock of fish within the marine ecosystem.

The SMBKC stock was declared overfished on October 22, 2018, because the estimated spawning biomass was below the minimum stock size threshold specified in the crab FMP. In order to comply with provisions of the Magnuson-Stevens Fishery Conservation and Management Act, a rebuilding plan must be implemented prior to the start of the 2020/2021 fishing season.

The St. Matthew Island blue king crab directed fishery has been closed since the 2016/2017 season. The St. Matthew Island Habitat Conservation Area (SMIHCA) was created in 2008 and expanded through Amendment 94 to the BSAI Groundfish FMP (NPFMC 2009) to protect blue king crab habitat; vessels fishing with non-pelagic trawl gear are prohibited from fishing in the SMIHCA. Other fishery closure areas include a 20 nm Steller sea lion closure around the southern tip of Hall Island (NMFS 2001) to trawling, hook-and-line, and pot fisheries for pollock, Pacific cod, and Atka mackerel. In addition, State jurisdictional waters (0 to 3 nm from shore) surrounding St. Matthew, Hall, and Pinnacle Islands are closed to the taking of king and Tanner crab and to commercial groundfish fishing.

This action is necessary to facilitate compliance with the requirements of the MSA to end and prevent overfishing, rebuild overfished stocks, and achieve optimum yield.

1.2. Requirements of the Magnuson-Stevens Act and National Standard Guidelines

This environmental assessment (EA) addresses alternatives for rebuilding the St. Matthew Island blue king crab stock as required under the MSA. Additionally, this action must be consistent with the ten National Standards of the MSA section 301(a)(1); fishery management plan provisions 303(a)(10) and 303(a)(14); rebuilding overfished fisheries 304(e); and national standard guidelines 50 CFR 600.310.

The SMBKC stock was declared overfished on October 22, 2018, because estimated biomass was below the minimum stock size threshold specified in the crab FMP. Section 304(e)(3) of the MSA requires the Council and Secretary of Commerce (Secretary) to develop and implement a rebuilding plan within two years of receiving notification from the Secretary that a stock is overfished, approaching an overfished condition, or has not made adequate progress towards rebuilding.

In order to comply with provisions of the MSA, the St. Matthew Island blue king crab rebuilding plan must be implemented prior to the start of the 2020/2021 fishing season.

1.2.1. Magnuson-Stevens Act Language on Rebuilding Overfished Stocks

Rebuilding of overfished stocks is required by the MSA section 304. The applicable section of the Act is provided below.
(e) REBUILDING OVERFISHED FISHERIES--

(1) The Secretary shall report annually to the Congress and the Councils on the status of fisheries within each Council's geographical area of authority and identify those fisheries that are overfished or are approaching a condition of being overfished. For those fisheries managed under a fishery management plan or international agreement, the status shall be determined using the criteria for overfishing specified in such plan or agreement. A fishery shall be classified as approaching a condition of being overfished if, based on trends in fishing effort, fishery resource size, and other appropriate factors, the Secretary estimates that the fishery will become overfished within two years.

(2) If the Secretary determines at any time that a fishery is overfished, the Secretary shall immediately notify the appropriate Council and request that action be taken to end overfishing in the fishery and to implement conservation and management measures to rebuild affected stocks of fish. The Secretary shall publish each notice under this paragraph in the Federal Register.

(3) Within two years of an identification under paragraph (1) or notification under paragraphs (2) or (7), the appropriate Council (or the Secretary, for fisheries under section 302(a)(3)) shall prepare a fishery management plan, plan amendment, or proposed regulations for the fishery to which the identification or notice applies--

(A) to end overfishing in the fishery and to rebuild affected stocks of fish; or

(B) to prevent overfishing from occurring in the fishery whenever such fishery is identified as approaching an overfished condition.

(4) For a fishery that is overfished, any fishery management plan, amendment, or proposed regulations prepared pursuant to paragraph (3) or paragraph (5) for such fishery shall--

(A) specify a time period for ending overfishing and rebuilding the fishery that shall--

(i) be as short as possible, taking into account the status and biology of any overfished stocks of fish, the needs of fishing communities, recommendations by international organizations in which the United States participates, and the interaction of the overfished stock of fish within the marine ecosystem; and

(ii) not exceed 10 years, except in cases where the biology of the stock of fish, other environmental conditions, or management measures under an international agreement in which the United States participates dictate otherwise;

(B) allocate both overfishing restrictions and recovery benefits fairly and equitably among sectors of the fishery; and

(C) for fisheries managed under an international agreement, reflect traditional participation in the fishery, relative to other nations, by fishermen of the United States.

(5) If, within the 2-year period beginning on the date of identification or notification that a fishery is overfished, the Council does not submit to the Secretary a fishery management plan, plan amendment, or proposed regulations required by paragraph (3)(A), the Secretary shall prepare a fishery management plan or plan amendment and any accompanying regulations to stop overfishing and rebuild affected stocks of fish within 9 months under subsection (c).
(6) During the development of a fishery management plan, a plan amendment, or proposed regulations required by this subsection, the Council may request the Secretary to implement interim measures to reduce overfishing under section 305(c)) until such measures can be replaced by such plan, amendment, or regulations. Such measures, if otherwise in compliance with the provisions of this Act, may be implemented even though they are not sufficient by themselves to stop overfishing of a fishery.

(7) The Secretary shall review any fishery management plan, plan amendment, or regulations required by this subsection at routine intervals that may not exceed two years. If the Secretary finds as a result of the review that such plan, amendment, or regulations have not resulted in adequate progress toward ending overfishing and rebuilding affected fish stocks, the Secretary shall--

(A) in the case of a fishery to which section 302(a)(3) applies, immediately make revisions necessary to achieve adequate progress; or

(B) for all other fisheries, immediately notify the appropriate Council. Such notification shall recommend further conservation and management measures which the Council should consider under paragraph (3) to achieve adequate progress.

1.2.2. National Standard 1 Guidelines

Further clarification on stock rebuilding under the Magnuson-Stevens Act for National Standard 1 (NS1) is provided in the excerpt below from the Final Rule on National Standard Guidelines published in the Federal Register on October 18, 2016 (81 FR 71858) and available on the NOAA Fisheries website: https://www.fisheries.noaa.gov/national/laws-and-policies/national-standard-guidelines

Sec. 600.310 National Standard 1—Optimum Yield.

(j) Council actions to address overfishing and rebuilding for stocks and stock complexes—

(1) Notification. The Secretary will immediately notify in writing a Regional Fishery Management Council whenever the Secretary determines that:

(i) Overfishing is occurring;

(ii) A stock or stock complex is overfished;

(iii) A stock or stock complex is approaching an overfished condition; or

(iv) Existing remedial action taken for the purpose of ending previously identified overfishing or rebuilding a previously identified overfished stock or stock complex has not resulted in adequate progress (see MSA section 304(e)).

(2) Timing of actions—

(i) If a stock or stock complex is undergoing overfishing. Upon notification that a stock or stock complex is undergoing overfishing, a Council should immediately begin working with its SSC (or agency scientists or peer review processes in the case of Secretarially-managed fisheries) to ensure that the ABC is set appropriately to end overfishing. Councils should evaluate the cause of overfishing, address the issue that caused overfishing, and reevaluate their ACLs and AMs to make sure they are adequate.

(ii) If a stock or stock complex is overfished or approaching an overfished condition. Upon notification that a stock or stock complex is overfished or approaching an overfished condition, a Council must prepare and implement an FMP, FMP amendment, or proposed regulations within two years of notification, consistent with the requirements of section 304(e)(3)
of the Magnuson-Stevens Act. Council actions should be submitted to NMFS within 15 months of notification to ensure sufficient time for the Secretary to implement the measures, if approved.

(3) Overfished fishery.—

(i) Where a stock or stock complex is overfished, a Council must specify a time period for rebuilding the stock or stock complex based on factors specified in Magnuson-Stevens Act section 304(e)(4). This target time for rebuilding (T_{target}) shall be as short as possible, taking into account: The status and biology of any overfished stock, the needs of fishing communities, recommendations by international organizations in which the U.S. participates, and interaction of the stock within the marine ecosystem. In addition, the time period shall not exceed 10 years, except where biology of the stock, other environmental conditions, or management measures under an international agreement to which the U.S. participates, dictate otherwise. SSCs (or agency scientists or peer review processes in the case of Secretarial actions) shall provide recommendations for achieving rebuilding targets (see Magnuson-Stevens Act section 302(g)(1)(B)). The above factors enter into the specification of T_{target} as follows:

(A) The minimum time for rebuilding a stock (T_{min}). T_{min} means the amount of time the stock or stock complex is expected to take to rebuild to its MSY biomass level in the absence of any fishing mortality. In this context, the term “expected” means to have at least a 50 percent probability of attaining the B_{msy}, where such probabilities can be calculated. The starting year for the T_{min} calculation should be the first year that the rebuilding plan is expected to be implemented.

(B) The maximum time for rebuilding a stock or stock complex to its B_{msy} (T_{max}).

(1) If T_{min} for the stock or stock complex is 10 years or less, then T_{max} is 10 years.

(2) If T_{min} for the stock or stock complex exceeds 10 years, then one of the following methods can be used to determine T_{max}:

   (i) T_{min} plus the length of time associated with one generation time for that stock or stock complex. “Generation time” is the average length of time between when an individual is born and the birth of its offspring,

   (ii) The amount of time the stock or stock complex is expected to take to rebuild to B_{msy} if fished at 75 percent of MFMT, or

   (iii) T_{min} multiplied by two.

(3) In situations where T_{min} exceeds 10 years, T_{max} establishes a maximum time for rebuilding that is linked to the biology of the stock. When selecting a method for determining T_{max}, a Council, in consultation with its SSC, should consider the relevant biological data and scientific uncertainty of that data, and must provide a rationale for its decision based on the best scientific information available. One of the methods listed in subparagraphs (j)(3)(i)(B)(2)(ii) and (iii) may be appropriate, for example, if given data availability and the life history characteristics of the stock, there is high uncertainty in the estimate of generation time, or if generation time does not accurately reflect the productivity of the stock.
(C) **Target time to rebuilding a stock or stock complex** ($T_{\text{target}}$). $T_{\text{target}}$ is the specified time period for rebuilding a stock that is considered to be as short a time as possible, taking into account the factors described in paragraph (j)(3)(i) of this section. $T_{\text{target}}$ shall not exceed $T_{\text{max}}$, and the fishing mortality associated with achieving $T_{\text{target}}$ is referred to as $F_{\text{rebuild}}$.

(ii) Council action addressing an overfished fishery must allocate both overfishing restrictions and recovery benefits fairly and equitably among sectors of the fishery.

(iii) For fisheries managed under an international agreement, Council action addressing an overfished fishery must reflect traditional participation in the fishery, relative to other nations, by fishermen of the United States.

(iv) **Adequate Progress.** The Secretary shall review rebuilding plans at routine intervals that may not exceed two years to determine whether the plans have resulted in adequate progress toward ending overfishing and rebuilding affected fish stocks (MSA section 304(e)(7)). Such reviews could include the review of recent stock assessments, comparisons of catches to the ACL, or other appropriate performance measures. The Secretary may find that adequate progress is not being made if $F_{\text{rebuild}}$ or the ACL associated with $F_{\text{rebuild}}$ is exceeded, and AMs are not correcting the operational issue that caused the overage, nor addressing any biological consequences to the stock or stock complex resulting from the overage when it is known (see paragraph (g)(3) of this section). A lack of adequate progress may also be found when the rebuilding expectations of a stock or stock complex are significantly changed due to new and unexpected information about the status of the stock. If a determination is made under this provision, the Secretary will notify the appropriate Council and recommend further conservation and management measures, and the Council must develop and implement a new or revised rebuilding plan within two years (see MSA sections 304(e)(3) and (e)(7)(B)). For Secretarially-managed fisheries, the Secretary would take immediate action necessary to achieve adequate progress toward rebuilding and ending overfishing.

(v) While a stock or stock complex is rebuilding, revising rebuilding timeframes (i.e., $T_{\text{target}}$ and $T_{\text{max}}$) or $F_{\text{rebuild}}$ is not necessary, unless the Secretary finds that adequate progress is not being made.

(vi) If a stock or stock complex has not rebuilt by $T_{\text{max}}$, then the fishing mortality rate should be maintained at its current $F_{\text{rebuild}}$ or 75 percent of the MFMT, whichever is less, until the stock or stock complex is rebuilt or the fishing mortality rate is changed as a result of the Secretary finding that adequate progress is not being made.

(4) **Emergency actions and interim measures.** If a Council is developing a rebuilding plan or revising an existing rebuilding plan due to a lack of adequate progress (see MSA section 304(e)(7)), the Secretary may, in response to a Council request, implement interim measures that reduce, but do not necessarily end, overfishing (see MSA section 304(e)(6)) if all of the following criteria are met:

(i) The interim measures are needed to address an unanticipated and significantly changed understanding of the status of the stock or stock complex;
(ii) Ending overfishing immediately is expected to result in severe social and/or economic impacts to a fishery; and

(iii) The interim measures will ensure that the stock or stock complex will increase its current biomass through the duration of the interim measures.

(5) Discontinuing a rebuilding plan based on new scientific information. A Council may discontinue a rebuilding plan for a stock or stock complex before it reaches Bmsy if the Secretary determines that the stock was not overfished in the year that the overfished determination (see MSA section 304(e)(3)) was based on and has never been overfished in any subsequent year including the current year.

(k) International overfishing. If the Secretary determines that a fishery is overfished or approaching a condition of being overfished due to excessive international fishing pressure, and for which there are no management measures (or no effective measures) to end overfishing under an international agreement to which the United States is a party, then the Secretary and/or the appropriate Council shall take certain actions as provided under Magnuson-Stevens Act section 304(i). The Secretary, in cooperation with the Secretary of State, must immediately take appropriate action at the international level to end the overfishing. In addition, within one year after the determination, the Secretary and/or appropriate Council shall:

(1) Develop recommendations for domestic regulations to address the relative impact of the U.S. fishing vessels on the stock. Council recommendations should be submitted to the Secretary.

(2) Develop and submit recommendations to the Secretary of State, and to the Congress, for international actions that will end overfishing in the fishery and rebuild the affected stocks, taking into account the relative impact of vessels of other nations and vessels of the United States on the relevant stock. Councils should, in consultation with the Secretary, develop recommendations that take into consideration relevant provisions of the Magnuson-Stevens Act and NS1 guidelines, including section 304(e) of the Magnuson-Stevens Act and paragraph (j)(3)(iii) of this section, and other applicable laws.

(3) Considerations for assessing “relative impact.” “Relative impact” under paragraphs (k)(1) and (2) of this section may include consideration of factors that include, but are not limited to: Domestic and international management measures already in place, management history of a given nation, estimates of a nation's landings or catch (including bycatch) in a given fishery, and estimates of a nation's mortality contributions in a given fishery. Information used to determine relative impact must be based upon the best available scientific information.

(l) Exceptions to requirements to prevent overfishing. Exceptions to the requirement to prevent overfishing could apply under certain limited circumstances. Harvesting one stock at its optimum level may result in overfishing of another stock when the two stocks tend to be caught together (This can occur when the two stocks are part of the same fishery or if one is bycatch in the other's fishery). Before a Council may decide to allow this type of overfishing, an analysis must be performed and the analysis must contain a justification in terms of overall benefits, including a comparison of benefits under alternative management measures, and an analysis of the risk of any stock or stock complex falling below its MSST. The Council may decide to allow this type of overfishing if the fishery is not overfished and the analysis demonstrates that all of the following conditions are satisfied:

(1) Such action will result in long-term net benefits to the Nation;
(2) Mitigating measures have been considered and it has been demonstrated that a similar level of long-term net benefits cannot be achieved by modifying fleet behavior, gear selection/configuration, or other technical characteristics in a manner such that no overfishing would occur; and

(3) The resulting rate of fishing mortality will not cause any stock or stock complex to fall below its MSST more than 50 percent of the time in the long term, although it is recognized that persistent overfishing is expected to cause the affected stock to fall below its B_{msy} more than 50 percent of the time in the long term.

1.2.3. Process for Determining Status of BSAI Crab Stocks

Each crab stock is annually assessed by the CPT and SSC to determine its status regarding whether (1) overfishing is occurring or the rate or level of fishing mortality for the stock is approaching overfishing, (2) the stock is overfished, or the stock is approaching an overfished condition, and (3) the catch has exceeded the ACL. If overfishing occurred or the stock is overfished, the MSA requires the NPFMC to immediately end overfishing and/or develop a plan to rebuild affected stocks. Status determination criteria for crab stocks are calculated using a five-tier system described below that accommodates varying levels of uncertainty of information. The five-tier system incorporates new scientific information and provides a mechanism to continually improve the status determination criteria as new information becomes available. Under the five-tier system, overfishing and overfished criteria and ABC levels for most stocks are annually formulated. The ACL for each stock equals the ABC for that stock. For crab stocks, The Overfishing Level (OFL) equals the maximum sustainable yield (MSY) and overfishing is determined by comparing the OFL with the catch estimates for that crab fishing year. Catch includes all fishery removals, including retained catch and discard mortality. Discard mortality is determined by multiplying the appropriate handling mortality rate by observer-based estimates of discards.

The OFL and ABC for each stock are estimated for the upcoming crab fishing year using a five-tier system, detailed in Table 1 and Table 2. First, a stock is assigned to one of the five tiers based on the availability of information for that stock and model parameter choices are made. Tier assignments and model parameter choices are recommended through the CPT process to the SSC. The SSC recommends tier assignments, stock assessment and model structure, and parameter choices, including whether the information is "reliable," for the assessment authors to use for calculating OFL and ABC.

For Tiers 1 through 4, once a stock is assigned to a tier (SMBKC is in Tier 4), the determination of stock status level is based on recent survey data and assessment models, as available. The stock status level determines the equation (Table 1) used in calculating the F_{OFL}. Three levels of stock status are specified and denoted by “a,” “b,” and “c” and the F_{MSY} control rule assigns F_{OFL} according to stock status level (Table 1). At stock status level “a,” current stock biomass exceeds the B_{MSY}. For stocks in status level “b,” current biomass is less than B_{MSY} but greater than a level specified as the “critical biomass threshold” (β). In stock status level “c,” the ratio of current biomass to B_{MSY} (or a proxy for B_{MSY}) is below β. At stock status level “c,” directed fishing is prohibited and an F_{OFL} at or below F_{MSY} would be determined for all other sources of fishing mortality in the development of the rebuilding plan. The SMBKC stock is in need of a rebuilding plan, however, because B_{2019}/B_{msy} is 31% (stock status “b”) according to the approved 2019 BSAI Crab Safe., directed fishing is permitted during rebuilding.

1.2.4. Status Determination for Tier 4 Crab Stocks

Tier 4 is for stocks like SMBKC for which essential life-history, recruitment information, and understanding are insufficient to achieve Tier 3. However, there is sufficient information for modeling that captures the essential population dynamics of the stock as well as the performance of the fisheries. The simulation modeling approach employed in the derivation of the annual OFLs captures the historical
performance of the fisheries as seen in observer data from the early 1990s to present and thus borrows information from other stocks as necessary to estimate biological parameters such as $\gamma$.

Explicit to Tier 4 are reliable estimates of biomass and natural mortality ($M$), and $F_{OFL}$ is calculated as the product of $M$ and a scalar, $\gamma$, such that $\gamma$ can be adjusted to account for differences in biomass measures. The proxy for $B_{MSY}$ under Tier 4 is the average biomass over a specified time period, with the understanding that the Council’s SSC may recommend a different value for a specific stock or stock complex to reflect the best available scientific information. For SMBKC $B_{MSY}^{proxy}$ is the average model estimate of mature male blue king crab biomass for the entire assessment period, 1978-2018 in the 2019 BSAI Crab SAFE.

If the information necessary to determine total catch is not available for a Tier 4 stock, then OFL and ACL are determined for retained catch. However for SMBKC, where all catch components are available, total catch is (1) non-directed discard mortalities; (2) directed fishery discard mortalities; and (3) directed fishery retained catch. In the future, as information improves, selectivity curves could be estimated for discard fisheries (directed and non-directed losses) as well as the directed fishery (retained catch) in the models.
Table 1. Five-Tier System for setting overfishing limits (OFLs) and Acceptable Biological Catches (ABCs) for crab stocks. The tiers are listed in descending order of information availability.

*35% is the default value unless the SSC recommends a different value based on the best available scientific information.

† An $F_{OFL} \leq F_{MSY}$ will be determined in the development of the rebuilding plan for an overfished stock.
Table 2. A guide for understanding the five-tier system.

- $F_{OFL}$ — the instantaneous fishing mortality ($F$) from the directed fishery that is used in the calculation of the overfishing limit (OFL). $F_{OFL}$ is determined as a function of:
  - $F_{MSY}$ — the instantaneous $F$ that will produce MSY at the MSY-producing biomass
    - A proxy of $F_{MSY}$ may be used; e.g., $F_x\%$, the instantaneous $F$ that results in $x\%$ of the equilibrium spawning per recruit relative to the unfished value
  - $B$ — a measure of the productive capacity of the stock, such as spawning biomass or fertilized egg production.
    - A proxy of $B$ may be used; e.g., mature male biomass
  - $B_{MSY}$ — the value of $B$ at the MSY-producing level
    - A proxy of $B_{MSY}$ may be used; e.g., mature male biomass at the MSY-producing level
  - $\beta$ — a parameter with restriction that $0 \leq \beta < 1$.
  - $\alpha$ — a parameter with restriction that $0 \leq \alpha \leq \beta$.

- The maximum value of $F_{OFL}$ is $F_{MSY}$. $F_{OFL} = F_{MSY}$ when $B > B_{MSY}$.
- $F_{OFL}$ decreases linearly from $F_{MSY}$ to $F_{MSY}(\beta-\alpha)/(1-\alpha)$ as $B$ decreases from $B_{MSY}$ to $\beta \cdot B_{MSY}$.
- When $B \leq \beta \cdot B_{MSY}$, $F = 0$ for the directed fishery and $F_{OFL} \leq F_{MSY}$ for the non-directed fisheries, which will be determined in the development of the rebuilding plan.
- The parameter, $\beta$, determines the threshold level of $B$ at or below which directed fishing is prohibited.
- The parameter, $\alpha$, determines the value of $F_{OFL}$ when $B$ decreases to $\beta \cdot B_{MSY}$ and the rate at which $F_{OFL}$ decreases with decreasing values of $B$ when $\beta \cdot B_{MSY} < B \leq B_{MSY}$.
  - Larger values of $\alpha$ result in a smaller value of $F_{OFL}$ when $B$ decreases to $\beta \cdot B_{MSY}$.
  - Larger values of $\alpha$ result in $F_{OFL}$ decreasing at a higher rate with decreasing values of $B$ when $\beta \cdot B_{MSY} < B \leq B_{MSY}$.
- The parameter, $b_3$, is the value for the annual buffer calculated from a $P^*$ of 0.49 and a probability distribution for the OFL that accounts for scientific uncertainty in the estimate of OFL.
- $P^*$ is the probability that the estimate of ABC, which is calculated from the estimate of OFL, exceeds the “true” OFL (noted as OFL’) ($P(\text{ABC}>\text{OFL'})$).

### 1.3. Scope of the Analysis

This EA relies heavily on the information and analysis contained in previous NEPA documents and Stock Assessment and Fishery Evaluation (SAFE) Reports. Relevant information from these documents are summarized in the appropriate chapters.

This EA also incorporates information from Amendment 94 to the BSAI groundfish FMP (NPFMC 2009), which established the current boundaries for the year-round non-pelagic trawl SMIHCA.

The Council on Environmental Quality regulations encourage agencies preparing NEPA documents to, “tier their environmental impact statements to eliminate repetitive discussions of the same issues and to
focus on the actual issues ripe for decision at each level of environmental review.” Specifically, 40 CFR 1502.20 states the following:

Whenever a broad environmental impact statement has been prepared (such as a program or policy statement) and a subsequent statement or environmental assessment is then prepared on an action included within the entire program or policy (such as a site specific action) the subsequent statement or environmental assessment need only summarize the issues discussed in the broader statement and incorporate discussions from the broader statement by reference and shall concentrate on the issues specific to the subsequent action. (40 CFR 1502.20)

This EA also relies heavily on the information and analysis contained in the Council’s 2019 BSAI Crab SAFE Report (NPFMC 2019), attached as an Appendix, and available from the Council web site at:

The annual SAFE Reports contain the status of the SMBKC stock as well as annual stock assessments for all ten BSAI crab stocks.

The preparation of a Regulatory Impact Review (RIR) is required under Presidential Executive Order (E.O.) 12866 (58 FR 51735, September 30, 1993). The requirements for all regulatory actions specified in E.O. 12866 are summarized in the following Statement from the E.O.:

In deciding whether and how to regulate, agencies should assess all costs and benefits of available regulatory alternatives, including the alternative of not regulating. Costs and Benefits shall be understood to include both quantifiable measures (to the fullest extent that these can be usefully estimated) and qualitative measures of costs and benefits that are difficult to quantify, but nevertheless essential to consider. Further, in choosing among alternative regulatory approaches, agencies should select those approaches that maximize net benefits (including potential economic, environmental, public health and safety, and other advantages; distributive impacts; and equity), unless a statute requires another regulatory approach.

Because neither alternative would involve any changes to federal regulations, the preparation of an RIR is not necessary and is not a part of this analysis.

1.4. SMBKC Management Area

The analyses presented here take into account the activities of directed SMBKC fisheries as well as other fisheries and non-fishing activities with the potential to impact the SMBKC stock. None of the actions to rebuild the SMBKC stock would redefine the fishery management unit in the FMP or introduce new or modified spatial management measures affecting SMBKC. Gear restrictions and prohibitions exist within the SMBKC stock area and are described in section 3.2.3.

The FMP authorizes the State of Alaska to define spatial management boundaries for crab stocks within the management unit. Under the State of Alaska’s spatial management scheme, the St. Matthew Island Section for blue king crab is the Northern District of Bering Sea king crab Registration Area Q (Figure 1), which includes the waters north of Cape Newenham (58°39’ N. lat.) and south of Cape Romanzof (61°49’ N. lat.).
2. Description of Alternatives

Ecosystem conditions are expected to be the primary limitation on the speed of rebuilding under any alternative. For all alternatives, the existing measures that minimize fishery impacts on SMBKC (described in Section 3.2.3) would be maintained throughout rebuilding since none are associated with sunset dates. Additionally, since the alternatives propose to achieve rebuilding only by limiting direct harvest of SMBKC, no alternatives propose to create new management measures within the BSAI Crab FMP or any other FMP.

2.1. Alternative 1, No Action

Under Alternative 1, the Council would not develop a rebuilding plan, and no Federal management response to address an overfished stock would be undertaken. Importantly, taking no action to establish a rebuilding plan for an overfished stock is a violation of the MSA. Harvest under this alternative would continue to be defined by the State harvest strategy as in Alternative 2 / Option 2 below. However, without a rebuilding plan, there would not be a mechanism to necessarily address operational issues that may constrain rebuilding, if they are present. Importantly, fishery management operations are not expected to constrain rebuilding under the existing ecosystem regime, which is the dominant limiting factor on stock productivity under any alternative.
2.2. Alternative 2, Establish a Rebuilding Plan

Under Alternative 2, a rebuilding plan would be established that would be consistent with the MSA and NS1 Guidelines on time for rebuilding, specifically rebuilding within a time (T_{target}) that is as short as possible, taking into account the status and biology of any overfished stocks of fish, the needs of fishing communities, recommendations by international organizations in which the United States participates, and the interaction of the overfished stock of fish with the marine ecosystems. The fastest rebuilding time (T_{min}), is calculated based on no fishing mortality (F=0). If T_{min} > 10 years, then the NS1 Guidelines provide other methods for defining maximum rebuilding time (T_{max}). Based on projections described in section 3.3.6, the time with a greater than 50% probability of rebuilding to B_{MSY} at F=0 (T_{min}) is **14.5 years**. Because T_{min} > 10 years, rebuilding times for the alternatives are evaluated relative to T_{max} as defined in the NS1 Guidelines as “T_{min} plus the length of time associated with one generation time for that stock or stock complex.” The estimated generation time for SMBKC is approximately 14 years, and therefore T_{max} is **28.5 years** ([T_{min}] + 14 years).

Under Alternative 2, a federal rebuilding plan for SMBKC will be incorporated into the BSAI King and Tanner Crab FMP by amending the FMP language to reflect the approved rebuilding alternative. The FMP authorizes the State to set preseason TACs and GHLs under State regulations, and seasons or areas are closed when the TAC or GHL is reached. The State must take into account the following factors, to the extent information is available, in developing harvest strategies or setting TACs and GHLs: (1) whether the ACL for that stock was exceeded in the previous year; (2) stock status relative to the OFL and ACL; (3) estimates of exploitable biomass; (4) estimates of recruitment; (5) estimates of thresholds; (6) market and other economic considerations; (7) additional uncertainty; and (8) any additional factors pertaining to the health and status of the stock or the marine ecosystem.

There are two options under Alternative 2 that consider alternative harvest scenarios during rebuilding:

**Option 1:** No directed fishing until the stock is rebuilt.

**Option 2:** Allow the directed fishery to open based on the state harvest strategy while the stock is rebuilding.

Although the SMBKC stock is in need of a rebuilding plan per the FMP, in the 2019 BSAI Crab SAFE B_{2019}/B_{mav} was 31% (stock status “b”, above the critical biomass threshold), so directed fishing is permitted during rebuilding, and Alternative 2 / Option 2 is a viable option (sections 1.2.3 and 1.2.4).

Under approval of Alternative 2/Option 1, the FMP language would be amended to reflect a prohibition on directed harvest of SMBKC until the stock is declared rebuilt. This would prohibit the State from setting a TAC or GHL under the State harvest strategy. Under Alternative 2/Option 2, the amended FMP language could either: 1) include the specific formulae for opening the SMBKC fishery provided in the current State harvest strategy or 2) state that no change in the harvest strategy should occur that would contribute to departure from the Council’s intended rebuilding timeline.

For Option 2, the State of Alaska’s Saint Matthew Island Section blue king crab harvest strategy (referred to as the “State harvest strategy”) is provided in the Alaska Administrative Code at 5 AAC 34.917 (below). The State harvest strategy is conservative compared to the federal control rule parameters for SMBKC. Under the state harvest strategy, directed fishing on SMBKC closes at higher biomass levels than the Council’s F_{OFL} control rule. Directed fishing is prohibited under the Council’s F_{OFL} control rule at B/B_{mav} = \beta = 25%, while the State harvest strategy prohibits fishing at biomass levels below B_{1978-2012} = 50% (Figure 2). Additionally, the values of the denominators are different: the State basis, B_{1978-2012}, is 3,880 t larger than current Council B_{MSY} (1978-2018) = 3,484 t.

5 AAC 34.917. Saint Matthew Island Section blue king crab harvest strategy.
(a) In the Saint Matthew Island Section, the commissioner may, by emergency order, open the blue king crab fishery only if the department's preseason survey estimate of mature male blue king crab equals at least 50 percent of the 1978–2012 average survey estimate of mature males.

(b) If the commercial blue king crab fishery is open under (a) of this section, and the preseason survey estimate of mature males is

1. at least 50 percent but less than 100 percent of the 1978–2012 average survey estimate of mature males, the number of legal males available for harvest will be no more than \(0.1 \times M \times \left(M / M_{1978-2012}\right)\), where \(M\) = the current year preseason survey estimate of mature males, and \(M_{1978-2012}\) = the 1978 – 2012 average survey estimate of mature males, or 25 percent of the preseason survey estimate of legal males, whichever is less;

2. equal to or greater than the 1978–2012 average survey estimate of mature males, the number of legal males available for harvest will be no more than 10 percent of the preseason survey estimate of mature males or 25 percent of the preseason survey estimate of legal males, whichever is less.

(c) In implementing this harvest strategy, the Alaska Board of Fisheries directs the department to use the best scientific information available and to consider the reliability of estimates of blue king crab, the manageability of the fishery, and any other factors it determines necessary to be consistent with sustained yield principles.

(d) For the purposes of this section,

1. "preseason survey estimate" means the

   (A) population number present at the time of the preseason survey as estimated directly by the area-swept method from annual trawl survey data, if a stock-assessment model is not used for abundance estimation;

   (B) model-estimated population number present at the time of the preseason survey times the estimated survey selectivity and catchability, if a stock-assessment model is used for abundance estimation;

2. "legal males" means all male blue king crab at least

   (A) 5.5 inches in width of shell; or

   (B) 120 millimeters in length of shell, if only shell length measurements are available in the preseason survey data;

3. "mature males" means all male blue king crab at least 105 millimeters in length of shell.
2.3. Monitoring Progress of the Rebuilding Plan

As required under NS1 Guidelines, the Secretary must ensure that progress made under a rebuilding plan is adequate. Throughout the rebuilding plan for SMBKC (Alternative 2), assessment surveys and biological data collection would be continued and help to facilitate the determination of adequate progress.

The NMFS eastern Bering Sea bottom-trawl survey provides data for annual assessment of the status of crab stocks in the BSAI, including SMBKC, and would continue throughout rebuilding. The BSAI Crab Plan Team would report stock status and progress towards the rebuilt level in the Stock Assessment and Fishery Evaluation (SAFE) Report for the king and Tanner crab fisheries of the BSAI.

Additionally, ADF&G and NMFS will monitor directed fishery catch (allowable only under Alternative 2/Option 2) and bycatch of blue king crabs in other fisheries (under any alternative). ADF&G requires full observer coverage (100%) for both catcher vessels and catcher processors participating in the fishery. Observers monitor harvest at sea and landings by catcher vessels shoreside processors. ADF&G reports the total harvest from the commercial fishery and that report will be included annually in the SAFE.

State and federal observer programs monitor bycatch with State coverage of the crab fisheries and federal monitoring of the groundfish trawl, pot and longline fisheries. Estimates of crab bycatch from all commercial fisheries will be reported annually in the SAFE and the BSAI Crab Plan Team will assess that bycatch relative to the expectations and assumptions of the rebuilding plan.

Management measures under the purview of ADF&G and NMFS contain levels of catch and bycatch at those prescribed in the rebuilding plan. If the combination of catch and bycatch were to approach the maximum level within any given year under the rebuilding plan, harvest can be capped through closure of directed harvest and area restrictions, if necessary, to reduce bycatch.
3. Environmental Assessment

There are four required components for an environmental assessment. The need for the proposal is described in Chapter 1 and the alternatives are described in Chapter 2. This chapter addresses the probable environmental impacts of the proposed action and alternatives. A list of agencies and persons consulted is included in Chapter 6.

This chapter evaluates the direct, indirect, and cumulative impacts of the alternatives and options on the various resource components. The socio-economic impacts of this action are described in detail in section 3.4 of this analysis.

Recent and relevant information, necessary to understand the affected environment for each resource component, is summarized in the relevant section. For each resource component, the analysis identifies the potential impacts of each alternative, and uses criteria to evaluate the significance of these impacts. If significant impacts are likely to occur, preparation of an EIS is required. Although an EA should evaluate economic and socioeconomic impacts that are interrelated with natural and physical environmental effects, economic and social impacts by themselves are not sufficient to require the preparation of an EIS (see 40 CFR 1508.14).

An environmental assessment must consider cumulative effects when determining whether an action significantly affects environmental quality. The Council on Environmental Quality (CEQ) regulations for implementing NEPA define cumulative effects as:

“the impact on the environment, which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time” (40 CFR 1508.7).

The concept behind cumulative effects analysis is to capture the total effects of many actions over time that would be missed if evaluating each action individually. Concurrently, the Council on Environmental Quality (CEQ) guidelines recognize that it is most practical to focus cumulative effects analysis on only those effects that are truly meaningful.

3.1. Methods

3.1.1. Resource Components Addressed in the Analysis

The proposed action is to establish a rebuilding plan for St. Matthew Island blue king crab. Extensive environmental analysis on all resource components is not needed in this document, because the proposed action is not anticipated to have environmental impacts on all resource components. The fishery has been closed since the 2016/2017 season and would remain closed for several years under the proposed action. Therefore there is no change anticipated to non-target species interactions, marine mammals, seabirds, or habitat. Table 3 identifies the components of the human environment that would be affected by establishing a rebuilding plan.
Table 3. Resources potentially affected by the proposed action and alternatives.

<table>
<thead>
<tr>
<th>Potentially affected resource component</th>

</table>

N = no impact anticipated by each alternative on the component.
Y = an impact is possible if each alternative is implemented.

3.1.2. Cumulative Effects Analysis

Council on Environmental Quality regulations require that the analysis of environmental consequences include a discussion of the action’s impacts in the context of all other activities (human and natural) that are occurring in the affected environment. Cumulative effects are those combined effects on the quality of the human environment that result from the incremental impact of the proposed action when added to other past, present, and reasonably foreseeable future actions, regardless of what Federal or non-Federal agency or person undertakes such other actions (40 CFR 1508.7). A discussion of the cumulative effects of the crab fisheries is provided in the Bering Sea Aleutian Islands Crab Fisheries Final Environmental Impact Statement/Regulatory Impact Review/Initial Regulatory Flexibility Analysis/Social Impact Assessment (Crab EIS) (NMFS 2004a). The past and current cumulative effects are discussed in the Alaska Groundfish Fisheries Final Programmatic Supplemental Environmental Impact Statement (NMFS 2004a). Both of these discussions are incorporated by reference.

This analysis discusses the cumulative effects of the following categories of reasonably foreseeable future actions identified for this action may have a continuing, additive, and meaningful relationship to the direct and indirect effects of the alternatives —

- ecosystem-sensitive management;
- traditional management tools;
- actions by other state, Federal, and international agencies; and
- private actions.

Ecosystem-sensitive management
Ecosystem-sensitive management is likely to benefit target species. The specific actions that will be taken to implement an ecosystem policy for fisheries management are unknown at this time; therefore, the significance of cumulative effects of ecosystem policy implementation on mortality, spatial and temporal distribution of the fisheries, changes in prey availability, and changes in habitat suitability are unclear. However, these actions may enhance the ability of stocks to sustain themselves at or above minimum stock size threshold (MSST) as ways are found to introduce ecosystem considerations into the management process.

Traditional management tools
Several ongoing management efforts are considered here in traditional management tools. These include ongoing management of the crab fisheries under crab rationalization, ACLs for crab stocks, rebuilding plans for other crab stocks, and management changes that may impact incidentally caught crab species in the Bering Sea groundfish fisheries.

The Crab Rationalization Environmental Impact Statement (NMFS 2004b) and Amendment 24 to the Crab FMP (NPFMC 2008a) incorporated into this analysis by reference assess the potential direct and indirect effects of crab fishery harvest levels in combination with other factors that affect physical and biological resource components of the Bering Sea and Aleutian Islands (BSAI) environment.
The Council took final action in 2010 on an analysis of implementing annual catch limits (ACLs) for all BSAI crab stocks, including the Saint Matthew Island blue king crab (SMBKC) stock, as well as a revised rebuilding plan for the eastern Bering Sea snow crab stock. No further constraint on crab fisheries are anticipated as a result of those actions. Acceptable biological catch (ABC) for BSAI crab stocks is annually specified by the Council’s SSC. This includes the ABC for the SMBKC stock regardless of the fact that the directed fishery is closed.

Accountability measures (AMs) are a required provision of the Magnuson-Stevens Fishery Conservation and Management Reauthorization Act of 2006 (Public Law 109-479) in conjunction with provisions for ACL requirements. The intent of AMs are to further protect a crab stock from overfishing by providing for a transparent response mechanism in the event that the established ACLs are exceeded.

Crab bycatch in the groundfish fisheries is not constraining for SMBKC stock recovery (Section 3.2.2) but will continue to be monitored. The Council is not considering management measures for further addressing bycatch in the groundfish fisheries such as additional time/area closures or hard caps on groundfish fisheries. If management measures are implemented in the future to reduce crab bycatch further, this could have an impact on groundfish fleet effort and distribution.

Other government actions
The Bureau of Ocean Energy Management, Regulation, and Enforcement expects that reasonably foreseeable future activities include development of oil and gas deposits over the next 15 to 20 years in Federal waters off Alaska. Potential environmental risks from the development of offshore drilling include the impacts of increased vessel offshore oil spills, drilling discharges, offshore construction activities, and seismic surveys. Adverse environmental impacts resulting from exploration and development in the future could impact salmon, halibut, and herring stocks. The extent to which these impacts may occur is unknown.

Private actions
Fishing activities by private fishing operations, carried out under the authority of the annual harvest specifications, are an important class of private action. The impact of these actions has been considered under traditional management tools.

While hatchery efforts for blue king crab are not currently active in the Saint Matthew Island region, there has been an effort underway as part of the Alaska King Crab Research and Rehabilitation program to assess the feasibility of stock enhancement of blue king crab. Blue king crab have been successfully cultured in the laboratory and field studies are proposed in the Bering Sea. The extent to which these actions may occur is unknown, and potential impacts could be assumed to be beneficial but are unknown.

Beyond the cumulative impacts discussed above and documented in the referenced analyses, no additional past, present, or reasonably foreseeable cumulative negative impacts on the biological and physical environment (including fish stocks, essential fish habitat, ESA-listed species, marine mammals, seabirds, or marine ecosystems), fishing safety, or consumers have been identified that would accrue from the proposed action.

3.2. Saint Matthew Island blue king crab

Blue king crab, Paralithodes platypus (Figure 3), are distributed in several disjunct locations of the North Pacific from Hokkaido, Japan, to southeastern Alaska (Figure 4). In the eastern Bering Sea, small populations are distributed around St. Matthew Island, the Pribilof Islands, St. Lawrence Island, and Nunivak Island. The State of Alaska divides the Bering Sea king crab Registration Area into the Pribilof Islands District and the Northern District. The St. Matthew Island Section for blue king crab in the Northern District of Bering Sea king crab Registration Area Q defines the spatial extent of the SMBKC
stock, which includes the waters north of Cape Newenham (58°39’ N. lat.) and south of Cape Romanzof (61°49’ N. lat.) (Figure 1).

The blue king crab is a shallow water species with adults found at an average depth of 70 m (NPFMC 2011). The reproductive cycle appears to be annual for the first two years and biennial thereafter (Jensen and Armstrong 1989), and mature crab migrate inshore seasonally where they molt and mate. Somerton and MacIntosh (1983) estimated SMBKC male size at the advent of sexual maturity to be 77 mm carapace length (CL), and the State of Alaska defines the lower size bound of functionally mature male SMBKC as ≥105 mm CL (Pengilly and Schmidt 1995). Otto and Cummiskey (1990) report an average growth increment of 14.1 mm CL for adult SMBKC males. Unlike red king crab, juvenile blue king crab do not form pods for protection from predators, but instead rely on cryptic coloration and suitable habitat such as cobble and shell hash.

For population modeling purposes age of recruitment to the fished stock is considered to be 7 years, and the resulting generation time, or average age of spawning individuals within the population, was considered to be 14 (B.Daly and A.Punt per comm). Generation time for SMBKC is needed for calculating T_{max} under NS1 Guidelines (Section 1.2.2) and defined as the average age of spawners in an unfished state, i.e.:

\[ G = \sum_{a=0}^{\infty} a N_a f_a / \sum_{a=0}^{\infty} N_a f_a \]

where N_a is number at age, and f_a is fecundity at age. For SMBKC and other crab, age is inferred from carapace length, which is not linear, but instead determined by growth via molting. Additionally, recruitment refers to the mature male size class (105 mm CL).

3.2.1. SMBKC Fishery Catches and Stock Biomass

The purpose of this section is to provide a discussion of the history of directed harvest levels for the entire assessment period (1978-2019; Table 4), while fleet and processor characteristics for the SMBKC fishery are provided in section 3.4.1.

The SMBKC fishery originally developed when ecological studies supporting oil exploration in the 1970s revealed the presence of crab in the area (Otto 1990). Ten U.S. vessels harvested 545 t in 1977, and harvests peaked in 1983 when 164 vessels landed 4,288 t (Nichols et al. 2019). The fishing seasons were generally short, early on, often lasting only a few days.

A directed fishery was prosecuted from 1977 to 1998, and harvest was fairly stable from 1986 to 1991, averaging 568 t annually. Harvest increased to a mean catch of 1,496 t during the 1991 to 1998 seasons until the fishery was declared overfished and closed in 1999, when the stock size estimate was below the MSST of 4,990 t.

Zheng and Kruse (2002) hypothesized a high level of SMBKC natural mortality from 1998 to 1999 as an explanation for the low catch per unit effort (CPUE) in the 1998 commercial fishery and 1999 to 2005 eastern Bering Sea trawl survey. In November 2000, Amendment 15 to the FMP for Bering Sea/Aleutian Islands king and Tanner crabs was approved to implement a rebuilding plan for the SMBKC stock (NPFMC 2000). The rebuilding plan included a State harvest strategy (5 AAC 34.917), area closures, and gear modifications. The State harvest strategy adopted into regulation for rebuilding included a minimum stock threshold at 2.9 million pounds of mature-males, a sliding harvest rate of 10-20% on mature-sized...
males, and a 40% cap on the harvest rate of legal males. In addition, all commercial crab fisheries near St. Matthew Island were restricted to fall and early winter to reduce the potential for bycatch mortality of vulnerable molting and mating SMBKC.

After a 10-year closure, NMFS declared the stock rebuilt in September 2009, and the fishery was reopened the next month with a TAC of 529 t. In that fishing season, seven vessels landed 209 t. The fishery remained open for the next three years with modest harvests, but declines in the NMFS trawl-survey estimate of stock abundance raised concerns, which prompted ADF&G to close the fishery again for the 2013/2014 season.

In 2014, the Board of Fisheries adopted a revised harvest strategy that better promotes stock rebuilding when the stock is at low levels. The revised harvest strategy established a lower stock threshold for opening the fishery, which is currently defined as 50 percent of the 1978-2012 average survey estimate of mature males; lowered the sliding harvest rate to 5-10% of the mature-sized males; and restricted the number of legal males that can be harvested to 25 percent or less. The fishery was reopened for the 2014/2015 season with a TAC of 297 t. In 2015/2016, the TAC was further reduced to 186 t. The fishery was closed during the 2016/2017 season, although the MMB estimate of 2.23 t, at the time, was above MSST (1.84 t). Fishery closures have been in place since the 2016/2017 crab fishing season.
Table 4. St. Matthew Island directed blue king crab pot fishery characteristics from 1978/79 to 2018/19. The Guideline Harvest Level and Total Allowable Catch (GHL/TAC) are equivalent and are in millions of pounds.

Based on the 2019 BSAI Crab SAFE, the model estimate of mature male biomass for the 2018/19 fishing season (1.15 kt) is below the minimum stock-size threshold (MSST; 1.74 kt), and so the stock is still
“overfished”. Figure 5 shows the annual mature male biomass estimates relative to annual MSST estimates from 2010-2019 based on the BSAI Crab SAFE. Note that values are based on historical assessments and not updated through the 2019 assessment.

Fishery closures, in combination with very low bycatch levels, have constrained removals of SMBKC below OFL, and so “overfishing” has not been occurring. Nevertheless, the 2019 BSAI Crab SAFE suggests that current spawning stock biomass is 52% of a hypothetical biomass if fishing had not occurred, via a “dynamic-B0 analysis”. This suggests that the impact of fishing is not insignificant and that under improved ecosystem conditions, reduced directed harvest would contribute to stock recovery.

![Graph showing annual mature male biomass estimates relative to annual MSST estimates from 2010-2019 based on the BSAI Crab SAFE.](image)

**Figure 5.** Annual mature male biomass (MMB) estimates relative to annual MSST estimates from 2010-2019 based on the BSAI Crab SAFE. Note that values are based on historical assessments and not the re-estimated MMB time series from the 2019 assessment.

### 3.2.2. Bycatch of SMBKC in other fisheries

The potential for SMBKC bycatch by groundfish fisheries to affect rebuilding times was evaluated quantitatively in projections described in Section 3.3.3 below. Existing spatial and temporal patterns of bycatch are described here.

Incidental catch of SMBKC has occurred in eastern Bering Sea groundfish fisheries and some other directed crab fisheries. The NMFS observer data suggest that variable, limited SMBKC bycatch has occurred in the eastern Bering Sea groundfish fisheries. Table 5 shows the range of groundfish fishery bycatch estimates of male SMBKC from 1978-2018 by gear category for all groundfish. A noteworthy fixed gear bycatch estimate of 69.7t occurred during an SMBKC fishery closure in 2007, however, non-target bycatch of male SMBKC has generally been less than 5 t, since 1991, compared to directed harvest of just over 1,000 t.

Figure 6 provides a statistical area map of the St. Matthews Island area that shows the amount of observed blue king crab bycatch in the groundfish fisheries using bar charts. The different colored bars represent historical (1996-2018) and recent (2014-2018) fixed gear bycatch of SMBKC as well as historic and recent trawl bycatch. Historic fixed gear bycatch has occurred in areas within the St. Matthew Island Habitat Conservation Area (SMIHCA) but has generally been reduced in the recent period. Low level
historical trawl bycatch and limited recent trawl bycatch occurred in the total stock area that extends beyond the SMIHCA.

Bycatch of blue king crab has also been observed historically in the eastern Bering Sea snow crab fishery, but in recent years it has generally been negligible. The St. Matthew Island golden king crab fishery, the only other commercial crab fishery in the area, occurs at depths that generally preclude blue king crab catch.

Figure 6. Comparison of spatial extent of historical (1996-2018) and recent (2014-2018) male SMBKC bycatch mortality in the groundfish fisheries in the St Matthew Island BKC stock area.

3.2.3. Existing Protections to SMBKC and SMBKC Habitat

The St. Matthew Island Habitat Conservation Area (SMIHCA; Figure 7) was created in 2008 and expanded through Amendment 94 to the BSAI Groundfish FMP (NPFMC 2009) to protect blue king crab habitat. Vessels fishing with non-pelagic trawl gear are prohibited from fishing in the SMIHCA to conserve blue king crab habitat. There has historically been some amount of trawl effort, targeting Pacific cod, just to the north of St. Matthew Island.
Other fishery closure areas include a 20nm Steller sea lion closure around the southern tip of Hall Island (NPFMC 2001; Figure 7) to trawling, hook-and-line, and pot fisheries for pollock, Pacific cod, and Atka mackerel. In addition, State jurisdictional waters (0 to 3 nm from shore) surrounding St. Matthew, Hall, and Pinnacle Islands are closed to the taking of king and Tanner crab and to commercial groundfish fishing.

It is challenging to quantitatively measure protections gained from fishery gear restricted areas. For example, estimating the magnitude of SMBKC biomass loss compared to current biomass if the closure areas had not been in place is difficult. Analyses provided for Amendment 94 to the BSAI Groundfish FMP suggest reductions of red king crab mortality following trawl gear modifications (Figure 8), which may also benefit blue king crab. The SMIHCA will continue to prohibit non-pelagic trawl gear throughout rebuilding.
Figure 8. Estimated mortalities of Chionoecetes opilio, C. bairdi, and red king crab after contact with conventional and modified sweeps. Rates have been adjusted for handling mortality based on mortality estimates from a control net. (Apparent negative mortality is a non-significant artifact of the control adjustment). From Amendment 94 EA-RIR-IRFA (NPFMC 2009)

3.2.4. Prevailing Ecosystem Conditions

SMBKC rebuilding will occur within the context of prevailing ecosystem conditions, which are most recently characterized in the “Ecosystem and Socioeconomic Profile” (ESP) included in the 2019 BSAI Crab SAFE. The ESP uses data collected from a variety of sources to generate ecosystem and socioeconomic indicators that may help explain trends for a given stock. The ESP process and products have been recommended by the CPT and SSC.

Five ecosystem indicators listed below were developed for SMBKC, and trends for these from 1980-present are illustrated in Figure 9. The indicators could be useful for informing progress during the rebuilding process.

1. Pre-recruit biomass
2. Bottom temperature
3. Cold pool extent
4. Benthic invertebrate biomass
5. Benthic predator biomass.

Pre-recruit biomass can be an indicator of future changes in mature male biomass and may also be useful as an early indicator of progress on stock recovery for the SMBKC. Bottom temperature peaked in 2018-2019, and there was a reduction in the cold pool extent. Bottom temperatures that exceed thermal optima for SMBKC could potentially induce movement to less favorable habitat. Invertebrate biomass and predator fish indicators peaked in 2016, and the peak in predators was dominated by Pacific cod.
Figure 9. Selected ecosystem indicators for SMBKC with time series ranging from 1980 – 2019. Upper and lower solid green horizontal lines are 90th and 10th percentiles of time series. Dashed horizontal line is the mean of the time series. The light green shaded area represents the most recent five years for mean and trend analysis. Source: 2019 BSAI Crab SAFE.

3.2.5. SMBKC ESP Conclusions/Recommendations

Projections (section 3.3.1) indicate that recruitment drives recovery time. A better understanding, therefore, of early life history processes and the continued development of indicators relevant to larval and juvenile SMBKC is needed. The availability of ESP indicators for SMBKC would be helpful during rebuilding, since the ESP results highlighted several vulnerabilities related to successful recruitment. The following set of additional considerations are provided based on the 2019 ESP:

Despite repeated fishery closures, SMBKC mature male biomass and recruitment estimates remain below-average following a 1989 regime shift in the Bering Sea, suggesting that environmental factors may be impeding recruitment success and stock recovery.

Highly specific thermal optimums and habitat requirements of SMBKC likely limit mobility in response to warmer than average bottom temperatures and shifting predator distributions in the Bering Sea.

Large catches of Pacific cod in the St. Matthew Island management boundary in 2016 preceded declines in BKC recruitment and the overfished declaration in 2018.
Trend modeling for ecosystem indicators revealed poor conditions for SMBKC in recent years, attributed to above average bottom temperatures, a reduction in the cold pool extent, and an increase in mean benthic predator biomass in the St. Matthew Island management boundary.

The ESP also recommends additional data gathering and research initiatives to address life history characteristics (i.e. growth-per-molt data and molting probabilities), as well as estimates for natural mortality, to aid in a better understanding of stage-specific vulnerabilities. In addition, process-based studies would identify links between larval survival, recruitment and environmental factors. Examining larval drift patterns and spatial distributions of mature BKC around St. Matthew Island in relation to habitat characteristics will help to inform essential fish habitat models and the development of a larval retention indicator. Furthermore, additional groundfish stomach data outside of the summer survey time series would help to refine our understanding of predation pressure across life history stages of SMBKC. Likewise, spring bottom temperatures prior to the summer bottom trawl survey may help to explain SMBKC distribution in relation to survey catchability.

3.3. Impacts of the Alternatives on Saint Matthew Island blue king crab

The alternatives described in Section 2, above, are evaluated in this section with respect to their differences in the estimated time for stock rebuilding, and those timelines are considered relative to stipulations of the NS1 Guidelines for Council specification of the target time for rebuilding (Ttarget). Under the Guidelines, both the minimum time to rebuild (Tmin) and the maximum time for rebuilding (Tmax) are calculated, and Ttarget cannot be greater than Tmax. According to the Guidelines, Tmin is the rebuilding time in the absence of any fishing mortality, and Tmax is, by default, 10 years, unless biology, the environment, or international agreements dictate otherwise. If Tmin is greater than 10 years, the Guidelines provide methods for calculating Tmax greater than 10 years.

Projections of the SMBKC stock indicate that a 50% probability of rebuilding to BMSY at F=0 under current environmental conditions, Tmin is 14.5 years. Because Tmin > 10 years, Tmax was calculated using the following method from the NS1 Guideline: “Tmin plus the length of time associated with one generation time for that stock or stock complex.” The estimated generation time for SMBKC is approximately 14 years, and therefore Tmax is 28.5 years ([Tmin] + 14 years), and, therefore, Ttarget must be less than 28.5 years.

3.3.1. Rebuilding Projections

Quantitative estimation of rebuilding timelines under the alternatives was done through modeled projections of population biomass. Each projection was identical in terms of starting population conditions, and multiple projection model parameterizations were explored to consider the range of stock productivity during rebuilding. The leading constraint on stock productivity is whether future ecosystem conditions will be conducive to successful recruitment of crab to the population. The protracted timeline for rebuilding under any alternative is a reflection of sub-optimal ecosystem conditions (summarized in section 3.2.4 above) both presently and throughout the rebuilding process.

3.3.2. Starting population conditions

All of the projections to estimate rebuild times are consistent with regard to starting population conditions and the measure of biomass that defines a rebuilt stock, i.e., the end point for rebuilding. Population quantities and parameter values (Table 6) were based on the accepted 2019 stock assessment for SMBKC (included as an Appendix). The stock assessment uses a three-stage Catch-Survey-Analysis (CSA) model configured within the GMACS framework (Webber et al. 2016) in order to facilitate an evaluation of model assumptions. The model estimates abundances of male SMBKC with carapace lengths (CLs)
greater than 90 mm within three length stages: stage 1: 90-104 mm CL; stage 2: 105-119 mm CL; and stage 3: CL ≥ 120 mm. The stage definitions are based on size at maturity - stage 2 (105 mm CL) and size at harvest - stage 3 (~120 mm or approximately 5.5 in CL). Additionally, the stages are consistent with the average growth increment of about 14 mm per molt (Otto and Cummiskey 1990).

All of the rebuilding projections were performed using a projection module coded into GMACS in early 2019 (A. Punt per comm). For each range of assumptions on F level and bycatch mortality a distribution of possible projections into the future was created (a minimum of 2,000 iterations). The resulting probability of recovery corresponds to the percentage of this distribution that results in a rebuilt stock (achieving a stock size equal to the B_{MSY} proxy in (Table 6).

In the projections, harvest under the State harvest strategy does not occur until biomass reaches the minimum necessary to trigger an opening. Trawl survey catches or estimated biomass can be used to trigger an opening of the fishery under the SHS, however, trawl survey catches were not modeled. Instead, the fishery did not open until the projected biomass reached a level analogous to the minimum survey catch threshold (50% of the long-term average from 1978 to 2012 per regulation). For this reason, at least in the projections, Alternative 2 Options 1 and 2 are not differentiable for the first 5-6 years of rebuilding.

Within the model, the beginning of the crab year is assumed to occur with the NMFS trawl survey, nominally assigned a date of July 1 and MMB is estimated for February 15, which is the federal management reference date for biomass. Each model year is split into five seasons and a scaled proportion of the natural mortality is applied in each. The seasons differ in terms of events and processes: season 1 (survey period), season 2 (natural mortality until pulse fishery), season 3 (pulse fishery), season 4 (natural mortality until spawning), and season 5 (natural mortality and somatic growth until June 30th). The timeframes for specific data inputs vary according to when data collection was initiated (observer data and pot surveys), or whether the fishery was open (fish tickets, trawl survey). Major data sources used in this assessment include annual directed-fishery retained-catch statistics from fish tickets; the annual NMFS eastern Bering Sea trawl survey; the ADF&G SMBKC pot survey; mean somatic mass given length category by year; size-frequency information from ADF&G crab-observer pot-lift sampling; and the NMFS groundfish-observer bycatch biomass estimates.

Figure 10 shows stations from which SMBKC trawl-survey and pot-survey data were obtained. Further information concerning the NMFS trawl survey as it relates to commercial crab species is available in Daly et al. (2014); see Vanek and Nault (2016) for a description of ADF&G SMBKC pot-survey methods. Note that the surveys cover different geographic footprints, and each has, in some years, encountered proportionally large numbers of male blue king crab in areas not covered by the other survey.
From the assessment, the OFL is the fishery-related mortality biomass associated with fishing mortality $F_{OFL}$. The SMBKC stock is currently managed as Tier 4, and only a Tier 4 analysis is presented here. Thus, given stock estimates or suitable proxy values of $B_{MSY}$ and $F_{MSY}$, along with two additional parameters $\alpha$ and $\beta$, $F_{OFL}$ is determined by the control rule:

$$F_{OFL} = \begin{cases} 
F_{MSY}, & \text{when } B/B_{MSY} > 1 \\
F_{MSY} \frac{(B/B_{MSY} - \alpha)}{(1-\alpha)}, & \text{when } \beta < B/B_{MSY} \leq 1 \\
F_{OFL} < F_{MSY} \text{ with directed fishery } F = 0 \text{ when } B/B_{MSY} \leq \beta
\end{cases}$$

where $B$ is quantified as mature-male biomass (MMB) at mating with time of mating assigned a nominal date of 15 February. Note that as $B$ itself is a function of the fishing mortality $F_{OFL}$ (therefore numerical approximation of $F_{OFL}$ is required). $F_{OFL}$ is taken to be full-selection fishing mortality in the directed pot fishery and groundfish trawl and fixed-gear fishing mortalities set at their model geometric mean values over the years for which there are data-based estimates of bycatch-mortality biomass.

The recommended Tier 4 convention is to use the full assessment period, currently 1978-2018, to define a $B_{MSY}$ proxy in terms of average estimated MMB and to set $\lambda = 1.0$ with assumed stock natural mortality $M = 0.18$ yr$^{-1}$ in setting the $F_{MSY}$ proxy value $\lambda M$. The parameters $\alpha$ and $\beta$ are assigned their default values $\alpha = 0.10$ and $\beta = 0.25$. The $F_{OFL}$, OFL, ABC, and MMB in 2019 for all scenarios are summarized in Table 6.

3.3.3. Effects of Bycatch by Groundfish Fisheries.

In section 3.2.2 Table 5 provides estimates of bycatch throughout the assessment period. With the exception of a remarkably high bycatch estimate of 69.7 t during a fishery closure in 2007, non-target bycatch of males SMBKC has generally been less than 5 t since 1991, compared to directed harvest of just over 1,000 t.

Rebuilding projections incorporated varying levels of assumed SMBKC bycatch by the groundfish fisheries (Table 7, Figure 11). The rebuilding curves with and without recent average (2014 - 2018) bycatch are indistinguishable. Additionally, bycatch at approximately 10x the average (max bycatch) added less than a year to the rebuilding time. The exaggerated bycatch scenario is not considered realistic, however, the potential for increased bycatch during rebuilding would be monitored during the rebuilding process.

As stated in section 2.3 above, the NMFS trawl survey would continue throughout rebuilding, and the BSAI Crab Plan Team would continue to report stock status and progress towards the rebuilt level in the annual SAFE Report. Additionally, ADF&G and NMFS monitor catches and bycatch of blue king crabs in other fisheries. ADF&G also requires full observer coverage on catcher vessels and catcher processing vessels to monitor catch and landings. ADF&G reports harvest from the commercial fishery and those data are included annually in the SAFE.

State and federal observer programs monitor bycatch with State coverage of the crab fisheries and federal monitoring of the groundfish trawl, pot, and longline fisheries Estimates of crab bycatch from all commercial fisheries will be reported annually in the SAFE. The BSAI Crab Plan Team will assess bycatch relative to the expectations and assumptions of the rebuilding plan. Additionally, if bycatch were to increase substantially, inseason actions could be taken to restrict harvest or area in the groundfish fisheries, if necessary, to reduce bycatch.

3.3.4. Constraints on Rebuilding from Recruitment

One of the primary drivers for future stock health for most shellfish stocks is recruitment, which is thought, in most species, to be highly variable and driven by environmental conditions. Thus, recruitment assumptions in the rebuilding projections was the focus of the projection options. While many different future recruitment assumptions were explored, three are presented here to encompass the breath of possibilities. The three options are:

1. Random draws of past recruitment from the entire time series (random_all_yrs),
2. Random draws from recent past recruitment with a time frame taken from the breakpoint analysis (Appendix D in the SAFE chapter) performed on this stock (random_recent), and
3. Parametrization of a Ricker stock-recruit relationship using all years of the model (Ricker).

Projections that estimated future recruitment from random draws from past recruitment of the entire time series of the model (random_all_yrs) were optimistic in the rebuilding time frame (Table 8, Figure 12). The recruitment assumption here allows for recruitment to reach high levels, like it has in the past, but the likelihood of such high recruitment occurring is low given the current climate regime in the Bering Sea according to recent ecosystem reports. The CPT concurred with the assessment author that these projections were overly optimistic for the current status of the stock and the environment.

Projections that estimated future recruitment from random draw from recent recruitment (random_recent), that was defined in the recruitment breakpoint analysis (Appendix D in the SAFE chapter, summarized below), were pessimistic in the rebuilding time frame, never rebuilding over a 100 year time frame (Table 8, Figure 13). While this recruitment assumption was realistic with respect to recent observed recruitment for this stock, it does not allow for recruitment to increase with time or improved stock conditions. Both the environment and stock status contribute to future recruitment, but which one is driving recruitment is not well defined, therefore it was considered pessimistic to assume that recruitment will never improve in the future. These projections do supply some of the expected outcomes in the worst-case scenario for this
stock where recruitment and rebuilding are not possible under the current climate regime (Table 8, Figure 13).

The third recruitment assumption explored was a parametrization of the Ricker stock-recruit relationship based on Punt et al. 2012. This assumption allows for recruitment to fluctuate with stock size and incorporates variability into the fluctuation considering that the stock-recruitment relationship is not strong for this stock (Figure 14). The variability in the stock-recruit relationship allows for the possibility of increases in recruit and subsequent increases in stock size in a gradual manner, unlike the overly optimistic or pessimistic outlooks of the other recruitment assumptions (Table 8, Figure 15).

For all of the alternatives, a Ricker stock-recruit relationship is proposed in the projections, since it incorporates stock status into the recruitment inputs and avoids choosing a time frame for random recruitment draws. This avoids conflict with the existing B_{MSY} proxy reference period, while also incorporating near-term ecosystem constraints on productivity. For estimating rebuilding times under the alternatives, it is considered unreasonable to use randomization that includes recruitment in the near future at levels seen prior to 1996. On the other hand, confining recruitment to the recent time frame can generate an unrealistically long rebuilding period.

Figure 12. Probability of recovery using projections with random recruitment (random_all_yrs) drawn from the entire time series (1978-2018) under two direct harvest scenarios, all having average recent bycatch mortality (2014-2018). Direct harvest is either zero (F=0) or is set to harvest under the State of Alaska harvest strategy (F=SHS).
Figure 13. Probability of recovery using projections with random recruitment (random_recent) drawn from recent model years as defined by the recruitment breakpoint analysis (1996-2018) under two direct harvest scenarios, all having average recent bycatch mortality (2014-2018). Direct harvest is either zero (F=0) or is set to harvest under the State of Alaska harvest strategy (F=SHS).

Figure 14. The approximated stock-recruit relationship for SMBKC based on methods from Punt et al. 2012. The solid line represents the fit, with the shaded area encompassing the 95% variability about this relationship.
3.3.5. Analysis of a Productivity Breakpoint

A breakpoint analysis explored the potential for historical changes in productivity that could have implications for the reference period for BMSY as well as recruitment inputs in projections (Figure 16). Methods used both Ricker and Beverton-Holt S-R methodologies and were similar to those used for Bristol Bay red king crab in 2017 (Zheng et al. 2017) and eastern Bering Sea Tanner crab in 2013 (Stockhausen 2013). Additionally, a “Sequential t-Test Analysis of Regime Shifts (STARS)” method was explored since it can be performed on any time series and does not rely on a stock recruitment relationship.

The two analyses converged on a brood stock breakpoint year of 1989 (Figure 17), which would produce a break in recruitment in 1996 and is consistent with characterizations of wide-scale changes in Bering Sea ecosystem conditions in 1989 (e.g., Overland et al., 2008). Recruitment success for SMBKC, as with many crab species, is driven by environmental conditions. In the Bering Sea, recent environmental conditions appear to be unfavorable for recruitment success for this stock, which may be due to a longer larval episode for blue king crab.

Although evidence clearly exists for a regime shift, redefining the BMSY reference point was not done for assessing impacts to the alternatives. Using Tier 4 definitions based on a revised (1996-2018) reference period, may ignore the influence of fishing mortality in the history of the stock, and is suggestive of “shifting baselines” according to discussions at the September 2019 CPT meeting. The current Tier 4 definition of BMSY based on 1978-2018 MMB is the effective rebuilding target, since it represents the BMSY proxy in the approved 2019 BSAI Crab SAFE.
Figure 16. Computed BMSY proxy (average mature male biomass) for the corresponding year ranges based on the 2019 assessment model with GMACS code updates.

Figure 17. Results from the Ricker stock-recruit breakpoint analysis. Upper graph: AICc vs. year of breakpoint for the 1-breakpoint models (circles) and AICc for the model with no breakpoint (horizontal line). Lower graph: probabilistic odds for all 1-breakpoint models (circles) and the no breakpoint model (horizontal solid line) relative to the model with the smallest AICc score. The dashed lines indicate the value for the model with the lowest AICc score (breakpoint in 1989).
3.3.6. Summary of Impacts to St Matthew blue king crab

Under any alternative or option, all of the existing measures that minimize fishery impacts on SMBKC would be expected to be maintained throughout rebuilding, since none are associated with sunset dates. These measures effectively prohibit use of non-pelagic trawl gear around St Matthew Island as defined by the St. Matthew Island Habitat Conservation Area (Figure 7). Additional protections are afforded by the adjacent modified gear trawl zone (Figure 7) and other fishery closure and gear restricted areas. In addition, State jurisdictional waters (0 to 3 nm from shore) surrounding St. Matthew, Hall, and Pinnacle Islands are closed to commercial king crab, Tanner crab, and groundfish fishing. Reductions in directing harvest impacts contributing to a recovered stock are expected to be additive to these existing measures for the SMBKC stock.

No alternative proposes management measures to reduce bycatch of SMBKC in the groundfish fisheries. The impacts of SMBKC bycatch in groundfish fisheries was thoroughly evaluated as a potential factor in stock recovery and analyses of rebuilding times factor in bycatch by groundfish fisheries at both average and maximum observed levels. In these projections, the time for stock recovery with average bycatch and with no bycatch are not differentiable (no effect). Additionally, in the “worst case scenario” projections that assume maximum observed bycatch in every year of rebuilding (14.5-25.5 years), the time for stock recovery is only minimally affected.

It is possible that rebuilding to BMSY may not occur under any alternative, given that the predominant constraint on stock productivity is likely ecosystem conditions. A complex suite of variables affect mortality of all life stages, but ecosystem conditions especially impact survival from age zero to approximately age 7, when male crab recruit to the mature male component of the population. As noted in section 3.2.4, stock productivity has been constrained by ecosystem conditions in recent years. Specifically:

- Despite repeated fishery closures, SMBKC mature male biomass and recruitment estimates remain below-average following a potential ecosystem regime shift in the Bering Sea in 1989.
- Highly specific thermal optimums and habitat requirements of SMBKC may limit mobility in response to warmer than average bottom temperatures and shifting predator distributions in the Bering Sea.
- Large increases in Pacific cod around St. Matthew Island in 2016 preceded declines in SMBKC recruitment and the overfished declaration in 2018.
- Poor conditions for SMBKC in recent years are attributed to above average bottom temperatures, a reduction in the cold pool extent, and an increase in mean benthic predator biomass in the St. Matthew Island management boundary.

The time to rebuild under Alternative 2/Option 2, the preferred alternative, is estimated to be 25.5 years, which is less than the estimate of $T_{max}$ (28.5 years). This option would allow for directed harvest, if an opening is triggered by threshold survey catches under the State harvest strategy. Because a rebuilding plan would be in place, compared to Alternative 1, constraints on fishing mortality could be made more conservative by further restricting fishery operations if necessary to ensure adequate progress.

Under Option 2, the State harvest strategy would prohibit fishing unless the estimate of mature male blue king crab is at least 50 percent of the 1978–2012 average survey estimate of mature males. In the harvest strategy at 5 AAC 34.917(d)(1) (A) and (B), the preseason survey estimate is defined as either the assessment model biomass estimate or, if an assessment model isn’t used, the EBS swept area trawl survey biomass estimate. Since an assessment model is used for estimating SMBKC MMB, annual
updates of the stock assessment for determination of stock status ($B_r/B_{msy}$) under the Council process would also be used for updating $B_r/B_{1978-2012}$ to determine openings under the State harvest strategy.

The State harvest strategy is conservative compared to the threshold for allowing harvest under the existing federal control rule parameters for SMBKC. Directed fishing is prohibited under the Council’s F_{OFL} control rule at $B/B_{msy} = 25\%$, while the State harvest strategy prohibits fishing at biomass levels below $B_r/B_{1978-2012} = 50\%$ (see Figure 2 in section 2.2). When the fishery does open under the State harvest strategy, harvest from the sloping portion of the State control rule is less than under the current parameter values for calculating ABC as a function of the federal F_{OFL} control rule (Figure 2). The larger denominator and threshold for opening should tend to delay directed fishing under the State harvest strategy relative to the Federal control rule and contributed to the States closure of directed fishing since 2016.

Additionally, the values of biomass estimated for each year in the assessment period are susceptible to adjustment as the assessment is updated with new data, so that new ratios of terminal year biomass ($B$) and biomass from the State and federal reference time frames ($B_{1978-2012}$ or $B_{msy}$) would be generated. In the current assessment, the value for the State basis, $B_{1978-2012}$, is 3,880 t compared to the $B_{MSY} = 3,484$ t. In the last four assessment updates (2016-2019), $B_{1978-2012}$ has been greater than $B_{MSY}$ (range +4% in 2016 to +10% in 2019).

Uncertainty in stock growth following closure of the fishery are illustrated in the rebuilding projections (Figure 18) and are likely related to delays in the onset of increases in recruitment. The mature male biomass (MMB) remains low in both the $F=0$ and $F=SHS$ projections for approximately the first 6 years, however during this time it is sloping upward. Figure 18 illustrates the average projected response of MMB under both Alt 2, Options 1 and 2, with the associated variability for each estimated MMB trend. This figure illustrates the substantial progress the MMB would make towards rebuilding (BMSY proxy) before the SHS could allow for some harvest.
Under both options, rebuilding trajectories for the initial five or six years are the same and the fishery would remain closed during this time period (Figure 18). After this initial period, the biomass is projected to be at a level that may allow harvest under the state harvest strategy in some years. Alternative 2/Option 2, would allow fisheries to occur under the state harvest strategy during the remaining 20-year period before the stock is rebuilt while Alternative 2/Option 1 would leave the fishery closed. However, the variability of biomass estimates in any given projection year indicates that future stock productivity is highly uncertain and rebuilding time is likely to deviate from the median values provided in Table 9. The area in Figure 18, during rebuilding (before the stock reaches B_{MSY}), where the 95% credible intervals overlap for both options illustrates the high variability associated with the biomass projections. The effects of stock productivity, a function of future ecosystem conditions, may overwhelm the effect of harvest under the Alternative 2 options. Nevertheless, this only serves to illustrate the uncertainty in future conditions. Under any productivity scenario, the median values suggest that rebuilding would be fastest under Alternative 2, Option 1 (14.5 years), however the great amount of variability associated with these estimates suggests that rebuilding could occur just as quickly under Option 2.

Table 9. Times to rebuild under Alternative 2 Options 1 and 2 based on projections using Tier 4 B_{MSY} proxy from the entire 1978-2018 time frame and Ricker stock-recruit relationship.

Conclusions

If the speed of rebuilding is the primary metric for benefits to the SMBKC stock, Alternative 2 / Option 1 is the most beneficial to the stock. Nevertheless, a protracted rebuilding period is expected even under the prohibition of directed fishing in Alternative 2, Option 1. No additional regulatory measures, such as reducing bycatch mortality (section 3.2.2) appear promising to accelerate rebuilding (Figure 15). Ecosystem conditions (section 3.2.4) may improve that would result in reduced natural mortality and increased production and are addressed during rebuilding through continued monitoring of ecosystem indicators. The allowance, in the projections, for recruitment to eventually increase and contribute to stock growth assumes that existing ecosystem conditions or other constraints on production will not continue indefinitely. Alternatively if current ecosystem conditions prevail, and recruitment remains at low levels, the population may take substantially longer to show rebuilding progress and may never reach the current B_{MSY} level.

3.4. Economic and Social Effects

This section provides background information on the fishery as well as the economic and social impacts of the alternatives including identification of the individuals or groups that may be affected by the action, and the nature, direction and magnitude of impacts if possible. The objective of this amendment is to rebuild the St. Matthew blue king crab stock to sustainable levels. The alternatives were discussed in section 2.

3.4.1. Description of the Fishery

The St. Matthew Island blue king crab fishery occurs in that portion of the Bering Sea north of the latitude of Cape Newenham at 58° 39’ N. lat. and south of the latitude of Cape Romanzof at 61° 49’ N. lat. This area, along with the rest of the Bering Sea, was fished by Japanese, Russian and other foreign vessels beginning in 1930. The last foreign fishing operations in this area concluded in 1974. The St. Matthew area was first exploited commercially by domestic fishers in 1977, when 10 vessels harvested 590 t. Catch and effort continued to increase with a peak harvest of 4,012 t taken in 1983 by 164 vessels. The annual harvest since that time has only exceeded 2,000 t once, in 1997. In 1998 the harvest was 1,347 t taken by 131 vessels. Significant declines in all components of the stock, including legal males, which fell below the minimum stock size threshold, prompted a complete fishery closure for the 1999 season.

In November 2000, Amendment 15 to the FMP for Bering Sea/Aleutian Islands king and Tanner crabs was approved to implement a rebuilding plan for the SMBKC stock (NPFMC 2000). After a closure for ten years while under the rebuilding plan, the St. Matthew Island blue king crab stock was declared rebuilt in 2009 and the fishery was opened for the 2009/2010 season, landing over 209 t worth almost $1 million. The fishery increased substantially for the next three years, landing 573-853 t annually worth between $6.2-8.7 million. Due to low area-swept survey results in 2013, the fishery was closed for the 2013/2014 season, but was subsequently reopened for 2014/2015 and 2015/2016. The fishery was substantially smaller during these years, however specific landings and value of the fishery cannot be reported due to confidentiality concerns. Low survey abundance since 2016 has led to fishery closures for the past three years (Table 10).

Season timing and duration have varied through the years based on catch limits and management changes. Over the 1977 to 1998 period, the SMBKC fishery was prosecuted during open seasons that varied in length and timing, with the earliest opening on June 7 in 1977, growing later over subsequent seasons to August 1 in 1982, September 1 in 1985, and September 16 in 1991, and September 15 from 1993 through 1998. Prior to 1982, SMBKC openings ranged from approximately 5 to 9 weeks, with the latest closing on September 3 after 19 days in both 1978 and 1980. Over subsequent years (when the fishery was open) prior to the crab rationalization program (implemented in 2005), openings in the fishery were limited to shorter spans of 1 to 11 days, with the latest closing in 1998 on September 26. With the implementation of the Crab Rationalization Program, the regulatory season for SMBKC was shifted to October 15 through February 1, with active fishing typically occurring within a period of 4-5 weeks beginning October 15, with final landings for the respective seasons occurring during early- to mid-November.

Trends in Quota Share holdings by geographic location since the implementation of the crab rationalization program in 2005 are shown in Figure 15. A majority of QS and persons holding QS are located in Washington state, however these numbers have been decreasing in recent years while both the number of holders and amounts of QS held in Alaska have increased.
Since the 2009/2010 season when the fishery reopened after the 10-year closure all participating vessels have been catcher vessels (no catcher processors have participated in the fishery). Participation increased from seven CVs in the 2009/2010 season to 18 in the 2011/2012 season. Participation dropped substantially after the 2013/2014 closure with only four CVs participating in the 2014/2015 season and three in the 2015/2016 season (Table 2). Vessels that have participated in the SMBKC fishery are primarily owned in communities in Washington and Alaska with a few vessels also participating from Oregon (Table 11). The geographic distribution of ownership has not changed demonstrably since the years prior to the 1999/2000 closure however there were substantially more vessels participating in the fishery before the crab rationalization program was implemented in 2005 (Table 3). A majority of the revenues from the SMBKC fishery over the past ten years have gone to vessels from Oregon and Washington while only 28% of annual average revenues from 2010-2012 was landed by vessels owned in Alaska (Table 13). Vessels participating in the fishery in 1995-1998 display similar patterns in the geographic distribution of revenue.

The vessels participating in the SMBKC fishery since 2010, on average, receive a fairly low percentage of their total revenues from the SMBKC fishery. Given fishery closures and data confidentiality requirements, reportable revenue information is only available for a few of the past 20 years. From 2010-2012 vessel dependence on SMBKC revenues was around 15% of annual average revenues (Table 14). This represents an increase in vessel dependence on SMBKC revenues from the years prior to the 1999 closure when average vessel dependence on SMBKC was under 9% (Table 15).

Figure 20 displays the percentage of average revenue over 2010-2015 (excluding 2014 when the fishery was closed), by fishery for SMBKC vessels based on their relative dependence on SMBKC. Vessels are grouped into quartiles based on the percentage of their revenue from 2010-2013 and 2015 that they receive from SMBKC. Vessels that participate in the SMBKC fishery generally participate in other crab fisheries, mainly the Bristol Bay red king crab and Bering Sea snow crab and to a lesser extent, Bering Sea Tanner crab East and West as well as groundfish. Those vessels with higher relative dependence on SMBKC generally have more evenly distributed portfolio of landings revenues, while those with lower SMBKC dependence are more heavily reliant on Bristol Bay red king crab and Bering Sea snow crab. Figure 17 shows the landed value of the other crab fisheries engaged in by SMBKC participants. These fisheries have also seen a substantial decline in value since 2015.
Table 16 provides information on ex-vessel gross revenue from the SMBKC fishery relative to total ex-vessel gross revenue from all areas, gears, and fisheries by community. Communities are identified by the historical ownership address for the vessels that participated in the SMBKC fishery from 2010 through 2012. Within these communities, both the number of vessels and the amount of revenue derived from SMBKC represent a relatively small portion of the overall community fishing effort and participation.
Of over 1,100 vessels that participate in commercial fishing in these communities, only 15 participate in the SMBKC fishery (Table 16). Ex-vessel revenue from the SMBKC fishery accounts for less than one percent of total ex-vessel revenues in these communities (Table 16).

Declines in participation over the past 10 years were also reflected in the processing sector. From 2009-2012, the communities of Dutch Harbor/Unalaska, St. Paul, and Akutan operated plants that received landings of SMBKC. Since the 2013/14 closure St. Paul is the only community that has received landings (Table 17). Between 2010 and 2012 the overall community processing dependence as measured by the amount of ex-vessel value processed in each community that is from the SMBKC fishery is just over 1.3% (Table 18).

BSAI King and Tanner Crab Buyback Program loan repayment

On January 12, 2004, the BSAI King and Tanner Crab Fishing Capacity Reduction Program was implemented (68 FR 69331) and funds were disbursed by January 19, 2005. In a reverse auction bidding process, this program permanently removed 25 fishing vessels and 62 fishing licenses and permits from BSAI crab fisheries. The Program is financed through an industry-funded, 30-year loan of $97,399,357 at a fixed rate of 6.54 percent administered by the NMFS Financial Services Division (FSD). The loan was split into six sub-loans based on the proportion of permits that were bought out for each of the following fisheries: 1) Bristol Bay Red King; 2) Bering Sea Snow (Opilio) and Tanner (Bairdi); 3) Aleutian Islands Brown (Golden) King; 4) Aleutian Island Red King; 5) Pribilof Red King and Pribilof Blue King; and 6) St. Matthew Blue King Crab fisheries. Fees for repayment of the loan are authorized under section 312(d)(2)(C) of the Magnuson-Stevens Act and are paid on harvests of the CR Program crab species. Harvesters are required to pay the fee and all parties making the first ex-vessel purchase of the crab (“fish buyers”) are required to collect the fee based on the crab's full delivery value, and account for and forward the fee revenue to NMFS to repay the loan. By regulation, the fee rate may not exceed 5% of the delivery value. The current fee rate for St. Matthew Blue King Crab is set at the maximum 5%. Table 19 shows the status of the SMBKC loan as of January 9, 2020. Payments were made towards the SMBKC sub-loan when the fishery was open, however because interest continues to accrue regardless of the status of the fishery, the current total amount owed on the loan is almost double the original loan amount. Simple interest accrues on the loan daily and payments are applied toward outstanding interest first and subsequently towards the principal balance (M. Sturtevant, personal communication, February 20, 2020). If the commercial fishery opens in the future, landings will be subject to a 5% fee to repay the loan. Interest will continue to accrue in the interim, so the total amount owed on the loan when the fishery opens is unknown. At an interest rate of 6.54%, the SMBKC sub-loan is accruing interest at a rate of $1,015.76 per day. Interest will continue to accrue at this pace until all outstanding interest is paid off; at which point subsequent payments will apply to the principal and interest will accrue on the remaining principal balance. Of the six original sub-loans, only the Aleutian Islands Brown (Golden) King Crab has been fully paid. Landings on any of the other five fisheries are subject to a harvest fee for repayment of the loan. As of January 9, 2020, the total amount owed on all remaining five sub-loans, including principal balance and outstanding interest was $73,296,241 (NMFS Financial Services Division).

Socioeconomic indicators

Socioeconomic indicators tracked in the Ecosystem and Socioeconomic Profile of the St. Matthew Blue King Crab stock in the Bering Sea (Fedewa et al. 2019) demonstrate a decline in most metrics of commercial value, constituent demand, community dependence and relative quantity and efficiency of fishing effort (Figure 22). It should be noted that the intermittent opening of the targeted SMBKC fishery over the last 20 years, creates substantial gaps in the time-series. Most socioeconomic indicators indicate zero (0) values when no fishery occurred, and the small number of vessels or processors participating in the fishery during some recent openings prevents reporting the value of some indicators for those years to protect confidentiality of associated landings and/or catch and effort data. Additionally, discontinuities in some data series due to changes in data collection methods limit reporting of indicator values to 1991 and later (Fedewa et al. 2019).
3.4.2. Expected Effects of the Alternatives

The Alternatives are described in detail in section 2. Alternative 1 would not implement a rebuilding plan. This would be a direct violation of the MSA, thus the effects of Alternative 1 are not analyzed further.

Alternative 2 would implement a rebuilding plan. Within Alternative 2, Option 1 would prohibit directed harvest throughout the rebuilding period. Option 2 would allow for directed harvest under the State of Alaska SMBKC harvest strategy. That strategy would prohibit directed harvest at any point during rebuilding when the State’s preseason survey estimate of mature male blue king crab is less than 50
percent of the 1978–2012 average survey estimate of mature males. If the preseason survey estimate allowed for a directed fishery, it would be subject to harvest control rules as described in section 2.2.

In the projection scenarios, the minimum time to reach a greater than 50% probability of rebuilding was 14.5 years under Option 1 and 25.5 years under Option 2 (Table 9). Therefore it is likely that under Alternative 2, Option 1, the directed SMBKC fishery would be closed for the next 14.5 years; while under Option 2, the fishery would likely open sooner (subject to the State harvest strategy) but would take 11 years longer to rebuild. There is a large amount of uncertainty associated with these timelines such that in some model runs the timelines overlap (Figure 18). No specific analysis was done to estimate how many years into the future the State harvest strategy would allow direct harvest under Option 2 (when the State’s preseason survey estimate of mature male blue king crab is projected to be at least 50 percent of the 1978–2012 average survey estimate of mature males). However, according to the recovery probability analysis, the fishing mortality under Option 1 (F=0) and Option 2 (F=SHR) begin to diverge at year five (Figure 15). Therefore, under Option 2 the fishery would likely be closed for the next five years. It is important to note that the purpose of the recovery probability analysis was not to estimate when the State harvest strategy would allow a directed fishery to open, but rather to compare the probability of stock recovery under different recruitment scenarios and differing levels of bycatch. Under these different recruitment and bycatch scenarios the year in which F=0 and F=SHR begin to diverge varies from year 3 to year 8. Therefore according to this analysis, under Alternative 2, Option 2, the fishery could be closed for the next three to eight years.

In either option under Alternative 2 there would be no directed SMBKC fishery in the near future, likely for three to eight years under Option 2 and longer under Option 1. Given that the fishery was last open in the 2015/2016 season, Alternative 2 represents a continuation of status quo. The direct social and economic impacts associated with closing the directed fishery have already occurred, therefore the short-term impacts of Alternative 2 are negligible. Inconsistent openings and reduced TACs over the last few years the fishery was open led to consolidation in participation at the vessel and processing level. Only three vessels participated during the last year the fishery was open (2015/2016), a substantial decline from the 18 vessels operating in 2011/2012 (the peak participation since the 2009/2010 season when the fishery reopened after the 10-year closure). Additionally, processing participation declined such that St. Paul is the only community that has processed SMBKC landings since 2013.

Given the intermittent openings and decreasing TACs of the targeted SMBKC fishery over the last 20 years, vessel and community dependence on SMBKC is relatively low (as described in section 3.4.1). Saint Paul is the only community that received landings since 2013. According to the Ecosystem and Socioeconomic Profile of the fishery (Fedewa et al 2019) the ex-vessel revenue share and the Local Quotient for Saint Paul both reached high values during 2010, concurrent with a peak in ex-vessel price. Large declines in both metrics over the subsequent open seasons, despite relatively high ex-vessel prices during the next four open SMBKC seasons indicate that both vessels and processors active during those years have shifted into other fisheries (Fedewa et al. 2019). Given the decline in value of other crab fisheries that SMBKC participants engage in (Figure 21) the ability to offset losses from the SMBKC fishery and maintain revenue streams in other fisheries may be limited. In contrast, the potential for opening the SMBKC fishery earlier under Alternative 2, Option 2, may allow participants to add SMBKC back into their portfolio to help offset the cumulative losses of other crab stock declines. The eastern Bering Sea Tanner crab (C. bairdi) fishery has been closed since 2016 while the western fishery has been closed two of the last four years. The Bering Sea snow crab fishery and the Bristol Bay red king crab fishery have remained open, however the relative value of these fisheries has declined in recent years (Figure 21). The potential for a SMBKC fishery under the state harvest policy would provide participants with additional flexibility which is particularly important under the current landscape of closures and declining values of other crab fisheries.
Long term social and economic effects of Alternative 2 are likely to be positive if the fishery rebuilds and can support a directed fishery. While the effects are similar under Option 1 and 2, the timeline of these effects may vary based on which Option is selected. Under Option 1, the fishery would remain closed longer, but rebuilding (and a fully open directed fishery) would likely occur sooner. Under Option 2, the State harvest strategy may open some fishing earlier, which could be beneficial to communities if harvesters are able to add SMBKC back into their fishing portfolio sooner, although this would likely increase the timeline for full rebuilding of the fishery (Table 9). Buyback loan repayment fees will be incurred on landings at any time the fishery is open, however interest accrues regardless of whether the fishery is open or closed so it is not possible to distinguish between the overall impact on loan repayments of Option 1 and Option 2.

Given that the fishery has been prosecuted after previous closed periods and TAC reductions, it is likely that some vessels would re-enter the fishery if rebuilding occurs or when the state harvest policy allows for fishing if Option 2 is selected. If future patterns of participation are consistent with those of previous years, benefits of rebuilding would likely accrue to Alaska, Washington and Oregon communities associated with vessels as identified in section 3.4.1 and the processing sector in St. Paul, AK. Detailed information about these communities is provided in NOAA Fisheries Fishing Community Profiles.

It is also worth considering the possibility that the fishery does not rebuild regardless of the Alternative and Option selected. The rebuilding timelines in Table 9 are estimates of the time to achieve a 50% probability of rebuilding. These projections allow for recruitment to eventually increase and contribute to stock growth and assume that existing ecosystem conditions or other constraints on production will not continue indefinitely. Given the uncertainty of these assumptions it is possible that regardless of the Alternative and Option selected the fishery may not rebuild. Under this scenario, communities will see no future benefits from the SMBKC fishery. The short-term impacts of this may be minimal as the fishery is currently closed, however this may impact long term planning for participants who would enter the fishery in future openings. Additionally, this would represent a substantial decline in asset value for current SMBKC QS holders.

3.5. NEPA Summary

One of the purposes of an environmental assessment is to provide the evidence and analysis necessary to decide whether an agency must prepare an environmental impact statement (EIS). The Finding of No Significant Impact (FONSI) is the decision maker's determination that the action will not result in significant impacts to the human environment, and therefore, further analysis in an EIS is not needed.

The Council on Environmental Quality regulations at 40 CFR 1508.27 state that the significance of an action should be analyzed both in terms of “context” and “intensity.” An action must be evaluated at different spatial scales and settings to determine the context of the action. Intensity is evaluated with respect to the nature of impacts and the resources or environmental components affected by the action. These factors form the basis of the analysis presented in this Environmental Assessment and the results of that analysis are summarized here for those criteria.

**Context: IDENTIFY THE APPROPRIATE SCOPE OF THE ACTION**

**Intensity:** Considerations to determine intensity of the impacts are set forth in 40 CFR 1508.27(b). Each consideration is addressed below in order as it appears in the NMFS Instruction 30-124-1 dated July 22, 2005, Guidelines for Preparation of a FONSI. The sections of the EA that address the considerations are identified.

1) Can the proposed action reasonably be expected to cause both beneficial and adverse impacts that overall may result in a significant effect, even if the effect will be beneficial?
Response: No. The proposed action implements a rebuilding plan for St Matthew Island blue king crab. It is not likely to significantly affect public health or safety, unique characteristics of the geographic area, or any of the places listed in Question number 8. The proposed action’s effects on the human environment are not likely to be highly uncertain or involve unique or unknown risks, nor are they expected to be controversial. The action is not precedent-setting, nor are the cumulative impacts of the proposed alternatives are determined to be significant. The proposed action is not expected to have effects on the habitat or ecosystem functioning due to protections that currently exist in regulation. These would not be changed by any of the alternatives. This action will not affect the introduction or spread of non-indigenous species.

2) Can the proposed action reasonably be expected to significantly affect public health or safety?

Response: Public health and safety are not expected to be adversely affected by rebuilding the SMBKC stock under the proposed action. The action alternatives would not modify existing safety regulations, authorized gear, the size or type of vessels that may be used in the fishery. The primary impact of the action alternatives is to close the fishery until sufficient progress in rebuilding allows it to be reopened. The preliminary preferred alternative seeks to accomplish this by allowing the fishery to reopen according to the State of Alaska harvest strategy.

Current fishing and delivery practices in the BSAI have been determined to promote the safety of life at sea to the extent practicable, and the considered action alternatives would not affect a vessel operator’s ability to make decisions that promote safety.

3) Can the proposed action reasonably be expected to result in significant impacts to unique characteristics of the geographic area, such as proximity to historic or cultural resources, park lands, prime farmlands, wetlands, wild and scenic rivers, or ecologically critical areas?

Response: No. This action affects commercial fishing in the offshore waters of the Bering Sea and Aleutian Islands (BSAI), it will not impact any historic or cultural resources, park land, prime farmlands, wetlands, wild and scenic rivers, or ecologically critical areas. Establishing a rebuilding plan for SMBKC will not impact any historic or cultural resources, park land, prime farmlands, wetlands, wild and scenic rivers, or ecologically critical areas.

4) Are the proposed action’s effects on the quality of the human environment likely to be highly controversial?

Response: No. The proposed action is not controversial, and no controversy was noted in public comments to the Council or NMFS about the data and information used to evaluate the impacts of the action on the human environment.

5) Are the proposed action’s effects on the human environment likely to be highly uncertain or involve unique or unknown risks?

Response: The effects on the human environment from the proposed action to rebuild the SMBKC stock are not expected to be highly uncertain or involve unique or unknown risk. The proposed action would implement required rebuilding measures through a closed fishery until conditions are met for reopening.

6) Can the proposed action reasonably be expected to establish a precedent for future actions with significant effects or represent a decision in principle about a future consideration?

Response: No. The implementation of a rebuilding plan for the SMBKC stock is being done in accordance with mandates from the Magnuson-Stevens Act and National Standard 1 Guidelines and is not precedent setting.
7) Is the proposed action related to other actions that when considered together will have individually insignificant but cumulatively significant impacts?

Response: No past, present, or reasonably foreseeable future actions were identified that would combine with the effects of this action to result in cumulatively significant impacts. These include ecosystem management, rationalization, and traditional management tools, which are likely to improve the protection and management of target and prohibited species, including targets of the BSAI crab fisheries.

Considering the direct and indirect impacts of the preferred alternative when added to the impacts of past and present actions previously analyzed in other documents (incorporated by reference in the EA) and the impacts of the reasonably foreseeable future actions listed above, the cumulative impacts of the proposed alternatives are determined to be not significant.

8) Can the proposed action reasonably be expected to adversely affect districts, sites, highways, structures, or objects listed in or eligible for listing in the National Register of Historic Places or may cause loss or destruction of significant scientific, cultural, or historical resources?

Response: No. Because this action affects commercial fishing in the waters of the BSAI, it will not impact any districts, sites, highways, structures, or objects listed or eligible for listing in the National Register of Historic Places. In addition, the EA did not identify any potential for the proposed action to cause loss or destruction of significant scientific, cultural, or historical resources.

9) Can the proposed action reasonably be expected to have a significant impact on endangered or threatened species, or their critical habitat as defined under the Endangered Species Act of 1973?

Response: No. This action will prohibit fishing for SMBKC until conditions are met that will allow reopening of the fishery and will not affect ESA species or their habitat.

10) Can the proposed action reasonably be expected to threaten a violation of Federal, state, or local law or requirements imposed for environmental protection?

Response: No. This action does not create any known violation of Federal, State, or local laws or requirements imposed for the protection of the environment.

11) Can the proposed action reasonably be expected to adversely affect stocks of marine mammals as defined in the Marine Mammal Protection Act?

Response: No. Rebuilding the SMBKC stock though closure of the fishery until conditions are met that will allow reopening is not expected to adversely affect marine mammals.

12) Can the proposed action reasonably be expected to adversely affect managed fish species?

Response: No. The proposed action would rebuild an overfished crab stock by temporarily prohibiting harvest and would not adversely affect managed fish species.

13) Can the proposed action reasonably be expected to adversely affect essential fish habitat as defined under the Magnuson-Stevens Fishery Conservation and Management Act?

Response: No. The proposed action would rebuild an overfished crab stock by temporarily prohibiting harvest and would not adversely affect essential fish habitat.

14) Can the proposed action reasonably be expected to adversely affect vulnerable marine or coastal ecosystems, including but not limited to, deep coral ecosystems?
Response: No. The proposed action would rebuild an overfished crab stock by temporarily prohibiting harvest and would not adversely affect marine or coastal ecosystems.

15) Can the proposed action reasonably be expected to adversely affect biodiversity or ecosystem functioning (e.g., benthic productivity, predator-prey relationships, etc.)?

Response: No. The proposed action would rebuild an overfished crab stock by temporarily prohibiting harvest and would not adversely affect biodiversity or ecosystem functioning.

16) Can the proposed action reasonably be expected to result in the introduction or spread of a nonindigenous species?

Response: No. The proposed action would rebuild an overfished crab stock by temporarily prohibiting harvest and would not introduce or spread nonindigenous species.

4. Magnuson-Stevens Act and FMP Considerations

4.1. Magnuson-Stevens Act National Standards

Consistency with the MSA is also addressed in section 1.2, above. Rebuilding overfished stocks is required by the MSA section 304(e), and therefore, this action is directly responsive to the MSA mandates.

Below are the 10 National Standards as contained in the Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act), and a brief discussion of how each alternative is consistent with the National Standards, where applicable. In recommending a preferred alternative, the Council must consider how to balance the national standards.

National Standard 1 — Conservation and management measures shall prevent overfishing while achieving, on a continuing basis, the optimum yield from each fishery for the United States fishing industry.

In terms of achieving “optimum yield” from the fishery, the Act defines “optimum,” with respect to yield from the fishery, as the amount of fish which—

(A) will provide the greatest overall benefit to the Nation, particularly with respect to food production and recreational opportunities, and taking into account the protection of marine ecosystems;

(B) is prescribed as such on the basis of the maximum sustainable yield from the fishery, as reduced by any relevant economic, social, or ecological factor; and

(C) in the case of an overfished fishery, provides for rebuilding to a level consistent with producing the maximum sustainable yield in such fishery.

The action alternative prevents overfishing of Saint Matthew Island blue king crab (SMBKC) by establishing a rebuilding plan that identifies catch levels that will rebuild the stock.

National Standard 2 — Conservation and management measures shall be based upon the best scientific information available.

Information in this analysis represents the most current, comprehensive set of information available to the North Pacific Fishery Management Council (Council), recognizing that some information (such as operational costs) is unavailable.
National Standard 3 — To the extent practicable, an individual stock of fish shall be managed as a unit throughout its range, and interrelated stocks of fish shall be managed as a unit or in close coordination.

This stock is managed as a single unit within the area defined as the stock boundary, and the rebuilding plan would be in effect throughout the management unit.

National Standard 4 — Conservation and management measures shall not discriminate between residents of different states. If it becomes necessary to allocate or assign fishing privileges among various United States fishermen, such allocation shall be; (A) fair and equitable to all such fishermen, (B) reasonably calculated to promote conservation, and (C) carried out in such a manner that no particular individual, corporation, or other entity acquires an excessive share of such privileges.

Nothing in the alternatives considers residency as a criterion for the Council’s decision. Residents of the various states, including Alaska and states of the Pacific Northwest, participate in the fishery affected by this decision. No discriminations are made based on residency or any other criteria.

National Standard 5 — Conservation and management measures shall, where practicable, consider efficiency in the utilization of fishery resources, except that no such measure shall have economic allocation as its sole purpose.

The wording of this standard was changed in the 2006 Magnuson-Stevens Act authorization, to consider rather than promote efficiency. Efficiency in the context of this change refers to economic efficiency, and the reason for the change, essentially, is to de-emphasize to some degree the importance of economics relative to other considerations (Senate Report of the Committee on Commerce, Science, and Transportation on S. 39, the Sustainable Fisheries Act, 1996). The analysis presents information relative to these perspectives and provides information on the economic risks associated with the proposed rebuilding plan.

National Standard 6 — Conservation and management measures shall take into account and allow for variations among, and contingencies in, fisheries, fishery resources, and catches.

All of the alternatives under consideration appear to be consistent with this standard.

National Standard 7 — Conservation and management measures shall, where practicable, minimize costs and avoid unnecessary duplication.

All of the alternatives under consideration appear to be consistent with this standard.

National Standard 8 — Conservation and management measures shall, consistent with the conservation requirements of this Act (including the prevention of overfishing and rebuilding of overfished stocks), take into account the importance of fishery resources to fishing communities by utilizing economic and social data that meet the requirements of National Standard 2, in order to (A) provide for the sustained participation of such communities, and (B) to the extent practicable, minimize adverse economic impacts on such communities.

A summary of the level of fishery engagement and dependence in communities with regard to SMBKC fishing is provided in section 3.4. Between 2010 and 2012 the overall community processing dependence as measured by the amount of ex-vessel value processed in each community that is from the SMBKC fishery is just over 1.3%. The sustained participation of the identified fishing communities is not put at risk by any of the alternatives being considered.
National Standard 9 — Conservation and management measures shall, to the extent practicable, (A) minimize bycatch, and (B) to the extent bycatch cannot be avoided, minimize the mortality of such bycatch.

The proposed action is specifically intended to control SMBKC catches through rebuilding. The practicability of the alternatives is demonstrated through existing fishery closures and mechanisms for establishing harvest limits.

National Standard 10 — Conservation and management measures shall, to the extent practicable, promote the safety of human life at sea.

The alternatives under consideration appear to be consistent with this standard. None of the alternatives or options proposed would change safety requirements for fishing vessels. No safety issues have been identified relative to the proposed action.

4.2. Section 303(a)(9) Fisheries Impact Statement

Section 303(a)(9) of the Magnuson-Stevens Act requires that a fishery impact statement be prepared for each FMP or FMP amendment. A fishery impact statement is required to assess, specify, and analyze the likely effects, if any, including the cumulative conservation, economic, and social impacts, of the conservation and management measures on, and possible mitigation measures for (a) participants in the fisheries and fishing communities affected by the plan amendment; (b) participants in the fisheries conducted in adjacent areas under the authority of another Council; and (c) the safety of human life at sea, including whether and to what extent such measures may affect the safety of participants in the fishery.

The EA/RIR prepared for this plan amendment constitutes the fishery impact statement. The likely effects of the proposed action are analyzed and described throughout the EA. The effects on participants in the fisheries and fishing communities are analyzed in section 3.4 No effects of the proposed action on safety of human life at sea are anticipated since no changes in fishery management measures are proposed. Based on the information reported in this section, there is no need to update the Fishery Impact Statement included in the FMP.

The proposed action affects the Saint Matthew Island blue king crab fishery in the EEZ off Alaska, which is under the jurisdiction of the North Pacific Fishery Management Council and the State of Alaska. Impacts on participants in fisheries conducted in adjacent areas under the jurisdiction of other Councils are not anticipated as a result of this action.

4.3. Council’s Ecosystem Vision Statement

In February 2014, the Council adopted, as Council policy, the following:

Ecosystem Approach for the North Pacific Fishery Management Council

Value Statement
The Gulf of Alaska, Bering Sea, and Aleutian Islands are some of the most biologically productive and unique marine ecosystems in the world, supporting globally significant populations of marine mammals, seabirds, fish, and shellfish. This region produces over half the nation’s seafood and supports robust fishing communities, recreational fisheries, and a subsistence way of life. The Arctic ecosystem is a dynamic environment that is experiencing an unprecedented rate of loss of sea ice and other effects of climate change, resulting in elevated levels of risk and uncertainty. The North Pacific Fishery
Management Council has an important stewardship responsibility for these resources, their productivity, and their sustainability for future generations.

**Vision Statement**

The Council envisions sustainable fisheries that provide benefits for harvesters, processors, recreational and subsistence users, and fishing communities, which (1) are maintained by healthy, productive, biodiverse, resilient marine ecosystems that support a range of services; (2) support robust populations of marine species at all trophic levels, including marine mammals and seabirds; and (3) are managed using a precautionary, transparent, and inclusive process that allows for analyses of tradeoffs, accounts for changing conditions, and mitigates threats.

**Implementation Strategy**

The Council intends that fishery management explicitly take into account environmental variability and uncertainty, changes and trends in climate and oceanographic conditions, fluctuations in productivity for managed species and associated ecosystem components, such as habitats and non-managed species, and relationships between marine species. Implementation will be responsive to changes in the ecosystem and our understanding of those dynamics, incorporate the best available science (including local and traditional knowledge), and engage scientists, managers, and the public.

The vision statement shall be given effect through all of the Council’s work, including long-term planning initiatives, fishery management actions, and science planning to support ecosystem-based fishery management.

In considering this action, the Council is being consistent with its ecosystem approach policy. This action establishes a plan for rebuilding the Saint Matthew blue king crab stock, taking into account the biology of the stock and prevailing ecosystem conditions. This is supportive of the Council’s intention to prevent overfishing and to adjust catch levels as necessary to account for uncertainty and ecosystem factors.

5. Preparers and Persons Consulted

**Lead Preparers:**

James Armstrong (NPFMC)
Anna Henry (NPFMC)
Katie Palof (ADF&G)
Megan Mackey (NMFS)

**Additional contributors and persons consulted:**

Karla Bush (ADF&G)
Anne Marie Eich (NMFS)
Diana Evans (NPFMC)
Josh Fortenbery (NOAA GC)
Mary Furuness (NMFS)
Jason Gasper (NMFS)
Kendall Henry (ADF&G)
Krista Milani (NMFS)
Mark Stichert (ADF&G)
Diana Stram (NPFMC)
Cathy Tide (NMFS)
