## Introduction

This document represents an effort to respond to comments made by the Joint Team Subcommittee on Pacific cod models (JTS), and the SSC on last year's assessment of the Pacific cod (Gadus macrocephalus) stock in the Aleutian Islands (AI) region (Thompson and Palsson 2015). Many of those comments were informed by the results of a CIE review of the AI Pacific cod assessment conducted during February 16-19, 2016. The website located at http://tinyurl.com/Pcod-cie-2016 contains every file vetted during the review process as well as the final reports from the three reviewers.

## Responses to SSC and Plan Team comments on assessments in general

SSC1 (10/15 minutes): "The Team Procedures document clarifies that the proposed development and testing of a naming convention should focus on tracking the modeling configurations used for a particular stock assessment. The rationale for this request is two-fold. First, it will help us understand how long it has been since a benchmark change in model configuration has occurred; second, it will help the reviewers and public to track model changes. Of the options presented in the Joint Plan Teams minutes, the SSC agrees that Option 4 has several advantages and recommends that this Option be advanced next year." As in last year's final assessment, Option 4a was used to number models in this preliminary assessment.

SSC2 (12/15 minutes): "The SSC reminds the authors and PTs to follow the model numbering scheme adopted at the December 2014 meeting." Given that comment SSC1 superseded the model numbering scheme adopted at the December 2014 meeting, it seems reasonable to assume that inclusion of this comment in the $12 / 15$ minutes was an error.

SSC3 (12/15 minutes):"Many assessments are currently exploring ways to improve model performance by re-weighting historic survey data. The SSC encourages the authors and PTs to refer to the forthcoming CAPAM data-weighting workshop report." Model 16.1 is the only model in this preliminary assessment that involves re-weighting survey data. The procedure used for this re-weighting is described under "Model Structures."

SSC4 (12/15 minutes): "The SSC recommends that assessment authors work with AFSC’s survey program scientist to develop some objective criteria to inform the best approaches for calculating $Q$ with respect to information provided by previous survey trawl performance studies (e.g. Somerton and Munro 2001), and fish-temperature relationships which may impact Q." The recent paper by Weinberg et al. (2016) is an example of the suggested collaboration. Although it dealt with survey trawl performance studies in the eastern Bering Sea, it might serve as a model for future collaborations dealing with the Aleutian Islands trawl survey.

## Responses to SSC and Plan Team comments specific to Aleutian Islands Pacific cod

Note: Following the procedure initiated in 2014, the task of developing recommendations for models to be included in this year's preliminary Pacific cod assessments (subject to review and potential revision by the SSC) was delegated to the JTS rather than the full Joint Plan Teams.

SSC5 (12/15 minutes): "One additional recommendation from the SSC is to examine weights-at-age of Pacific cod by area." This recommendation will be addressed in the final assessment.

JTS1 (5/16 minutes): "For the AI, the JTS recommended that the following models be developed for this year's preliminary assessment:

- Model 1: AI Model 13.4, the final model from 2015 (Tier 5 random effects model)
- Model 2: Like AI Model 15.7, but simplified as follows:
o Weight abundance indices more heavily than sizecomps.
o Use the simplest selectivity form that gives a reasonable fit.
o Do not allow survey selectivity to vary with time.
o Do not allow survey catchability to vary with time.
o Do not allow strange selectivity patterns.
o Estimate trawl survey catchability internally with a fairly non-informative prior.
- Model 3: Like AI Model 15.7, but including the IPHC longline survey data and other features, specifically:
o Do now allow strange selectivity patterns.
o Estimate trawl survey catchability internally with a fairly non-informative prior.
o Estimate catchability of new surveys internally with non-restrictive priors.
o Include additional data sets to increase confidence in model results.
o Include IPHC longline survey, with "extra SD."
- Model 4: Like Model 3 above, but including the NMFS longline survey instead of the IPHC longline survey.
- Model 5: Like Models 3 and 4 above, but including both the IPHC and NMFS longline survey data.
- Model 6: Like AI Model 15.7, except:

0 Use the post-1994 AI time series (instead of the post-1986 time series).
o Do not allow strange selectivity patterns.
o Estimate trawl survey catchability internally with a fairly non-informative prior."
All of the requested models are included in this preliminary assessment (see also comment SSC6). Note that some points in the above lists of features may be somewhat duplicative, but were included by the JTS in order to address specific comments made by CIE reviewers. As noted in the JTS meeting minutes, the model numbers used above were intended just as placeholders, until final model numbers could be assigned, following the adopted model numbering convention (see comment SSC1). Application of the numbering convention resulted in the following model numbers:

| JTS "placeholder" model number: | 1 | 2 | 3 | 4 | 5 | 6 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Final model number: | 13.4 | 16.1 | 16.2 | 16.3 | 16.4 | 16.5 |

SSC6 (6/16 minutes):"The SSC accepts the JTS recommendations for models to bring forward in the 2016 assessment...." See comment JTS1.

SSC7 (6/16 minutes): "The SSC agrees with CIE recommendations to use all reasonable data sources that are available, although the use of the longline survey data in the model has been attempted in the past with little success. As the author noted, survey indices were generally negatively correlated with model-estimated biomass in past assessments. The use of 'extra SD' in the proposed models for both regions is a reasonable approach to deal with this issue." Internally estimated increments to the logscale standard errors for the IPHC and NMFS longline survey indices are reported in Table 2.1.7.

## Data

The data used in this preliminary assessment are identical to those used in last year's final assessment (Thompson and Palsson 2015), except for:

- the addition of IPHC survey data (abundance index and size composition) in Models 16.2 and 16.4; and
- the addition of NMFS longline survey data (abundance index and size composition) in Models 16.3 and 16.4.

The following table summarizes the sources, types, and years of data included in the data file for the Tier 5 model—Model 13.4:

| Source | Type | Years |
| :--- | :--- | :--- |
| AI bottom trawl survey | Biomass | 1991, 1994, 1997, 2000, 2002, |
|  |  | $2004,2006,2010,2012,2014$ |

The following table summarizes the sources, types, and years of data included in the data files for at least one of the Tier 3 models-Models 16.1-16.5 (italics denote data not included in last year's assessment):

| Source | Type | Years |
| :--- | :--- | :--- |
| Fishery | Catch biomass | 1977-2015 |
| Fishery | Size composition | 1978-1979, 1982-1985, 1990-2015 |
| AI bottom trawl survey | Numerical abundance | 1991, 1994, 1997, 2000, 2002, |
|  |  | 2004, 2006, 2010, 2012, 2014 |
| AI bottom trawl survey | Size composition | 1991, 1994, 1997, 2000, 2002, |
|  |  | 2004, 2006, 2010, 2012, 2014 |
| AI bottom trawl survey | Age composition | 2002, 2006, 2010, 2012, 2014 |
| IPHC longline survey | Relative abundance | $1997-2014$ |
| IPHC longline survey | Size composition | 2015 |
| NMFS longline survey | Relative abundance | $1996-2014$ (even years only) |
| NMFS longline survey | Size composition | $1996-2014$ (even years only) |

Relative abundance data from the IPHC and NMFS longline surveys are shown in Table 2.1.1, and size composition data from those two surveys are shown in Table 2.1.2.

Multinomial input sample sizes were specified using procedures similar to those used in the EBS Pacific cod assessment (Thompson 2015): 1) Records with fewer than 400 observations were omitted. 2) The sample sizes for fishery length compositions from years prior to 1999 were tentatively set at $16 \%$ of the actual sample size, and the sample sizes for fishery length compositions after 1998 and all survey length compositions were tentatively set at $34 \%$ of the actual sample size. 3) All sample sizes were adjusted proportionally to achieve a within-fleet average sample size of 300 (i.e., the fishery sample sizes average

300, as do the survey sample sizes). Age composition input sample sizes are obtained by scaling the number of otoliths read so that the average is 300 .

## Model structures

All of the models presented in this preliminary assessment were developed using Stock Synthesis (SS, Methot and Wetzel 2013). The version used to run all models was SS V3.24u, as compiled on 8/29/2014. Stock Synthesis is programmed using the ADMB software package (Fournier et al. 2012). The user manual for SS V3.24s, along with a "change log" documenting revisions between V3.24s and V3.24u, is available at:
https://drive.google.com/a/noaa.gov/?tab=mo\#folders/0Bz1UsDoLaOMLN2FiOTI3MWQtZDQwOS00Y WZkLThmNmEtMTk2NTA2M2FjYWVh.

## Developing the models requested by the Joint Team Subcommittee

Six models are presented in this preliminary assessment. Model 13.4 is a Tier 5 model and has been the accepted model since 2013. The other five models (Models 16.1-16.5) are all Tier 3 models, and are variants of Model 15.7, which was introduced in last year's final assessment as a modification of Model 15.3 from last year's preliminary assessment (where it was labeled "Model 3").

Details of Model 15.7 are described in the next two subsections. The distinguishing features of Models 16.1-16.5 were listed above (see comment JPT1 under "Responses to SSC and Plan Team comments specific to Aleutian Islands Pacific cod," above).

In the minutes of its May 2016 meeting, the JTS recognized that some of the terms used in the descriptions of its requested models were somewhat subjective and that, in making those requests, the assessment author would need to determine:

1. How to measure the "weight" assigned to abundance indices and size composition data in the same units (Model 16.1).
2. What constitutes a "reasonable fit" to the size/age composition data (Model 16.1).
3. What constitutes a "strange" selectivity pattern (Models 16.1-16.5).
4. What constitutes a "fairly non-informative prior" (Models 16.1-16.5).

These issues were addressed as follows:

1. The relative "weight" assigned to abundance indices and size composition data was determined by comparing the average spawning biomasses from three models:
A. a model with a specified set of likelihood "emphasis" $(\lambda)$ values, with each $\lambda \geq 1.0$;
B. a model in which $\lambda$ for the abundance data was set equal to 0.01 while each $\lambda$ for the size composition data (fishery and survey) was left at the value specified in model A; and
C. a model in which each $\lambda$ for the size composition data (fishery and survey) was set equal to 0.01 while each $\lambda$ for the abundance data was left at the value specified in model B. Model B was taken to represent model A with the abundance data "turned off," while model C was taken to represent model A with the size composition data "turned off" (a $\lambda$ value of 0.01 rather than 0 was used for to represent "turning off" a data component because some parameters might prove inestimable if that data component were removed entirely). The abundance data in model A were determined to receive greater weight than the size composition data in that model if the absolute value of the proportional change in spawning biomass between models B and A exceeded the analogous value between models C and A. The JTS requested that this criterion (giving greater weight to abundance data than size composition data) be included in Model 16.1
only. As it turned out, leaving $\lambda$ at the default value of 1.0 for all data components was insufficient to satisfy this criterion. However, by leaving $\lambda$ for the size composition components (fishery and trawl survey) at the default value of 1.0 and increasing $\lambda$ on all other components to 2.0 was sufficient to satisfy this criterion.
2. To focus on the ability of a particular functional form to fit the data, independent of the absolute values of the sample sizes specified for the associated multinomial distribution or $\lambda$ values, weighted coefficients of determination $\left(R^{2}\right)$, computed on both the raw and logit scales, were used to measure goodness of fit (the equations below are written in terms of age composition; the equations for size compositions are analogous):

$$
R^{2}=\sum_{y=y \min }^{y \max }\left(w_{y} \cdot\left(1-\frac{\sum_{a=0}^{a \max }\left(\text { Pobs }_{a, y}-\text { Pest }_{a, y}\right)^{2}}{\sum_{a=0}^{a m a x}\left(\text { Pobs }_{a, y}-\text { Pobs }_{a v e, y}\right)^{2}}\right)\right),
$$

and

$$
R^{2}=\sum_{y=y \min }^{y \max }\left(w_{y} \cdot\left(1-\frac{\sum_{a=0}^{a m a x}\left(\operatorname{logit}\left(\text { Pobs }_{a, y}\right)-\operatorname{logit}\left(\text { Pest }_{a, y}\right)\right)^{2}}{\sum_{a=0}^{\operatorname{amax}}\left(\operatorname{logit}\left(\text { Pobs }_{a, y}\right)-\operatorname{logit}\left(\text { Pobs }_{a v e, y}\right)\right)^{2}}\right)\right)
$$

where

$$
w_{y}=\frac{n_{y}}{\sum_{i=y \min }^{y \max } n_{i}},
$$

Pobs $_{a, y}$ represents the observed proportion at age $a$ in year $y$, Pobs $_{\text {ave, } y}$ represents the average (across ages) observed proportion in year $y$, Pesta,y represents the estimated proportion at age $a$ in year $y$, and $n_{y}$ represents the specified multinomial sample size in year $y$. To guard against the possibility of achieving misleadingly high $R^{2}$ values by extending the size or age range beyond the sizes or ages actually observed, the data were filtered by removing all records with Pobs saty $<$ 0.001 prior to computing the $R^{2}$ values. A fit was determined to be "reasonable" if it yielded both an $R^{2}$ value of at least 0.99 on the raw scale and an $R^{2}$ value of at least 0.70 on the logit scale. As with \#1 above, the JTS requested that this criterion (simplest selectivity function that gives a reasonable fit) be included in Model 16.1 only. Because the "random walk with respect to age" selectivity function gave a reasonable fit, the function was simplified in successive steps first by removing all time-variability, then by switching to a double-normal function. However, neither of these changes resulted in a reasonable fit, so the random walk functional form with timevariability (for the fishery only) was retained.
3. In general, a "strange" selectivity pattern was defined here as one which was non-monotonic (i.e., where the signs of adjacent first differences changed), particularly if the first differences associated with sign changes were large (in absolute value), and particularly if sign changes in first differences occurred at relatively early ages. Specifically, an index of "strangeness" was defined as follows:
A. Age-specific weighting factors $P_{a}$ were calculated as the equilibrium unfished numbers at age expressed as a proportion of equilibrium unfished numbers.
B. For each year, age-specific first differences in selectivity $\Delta_{a, y}$ were calculated.
C. "Strangeness" was then calculated as:
$\left(\frac{1}{y \max -y \min +1}\right) \cdot \sum_{y=y \min }^{y \max } \sqrt{\sum_{a=2}^{a \max }\left(P_{a} \cdot\left(\left(\operatorname{sign}\left(\Delta_{a, y}\right) \neq \operatorname{sign}\left(\Delta_{a-1, y}\right)\right) \cdot\left(\Delta_{a}\right)^{2}\right)\right)}$, where the expression $\operatorname{sign}\left(\Delta_{a, y}\right) \neq \operatorname{sign}\left(\Delta_{a-1, y}\right)$ returned a value of 1 if the sign of $\Delta_{a, y}$ differed from the sign of $\Delta_{a-1, y}$ and a value of 0 otherwise. This index attains a minimum of 0 when selectivity is constant across age (or varies monotonically) and a maximum of 1 if selectivity alternates between values of 0 and 1 at all pairs of adjacent ages.
A time series of selectivity at age (for a given fleet) was determined to be "strange" if the index described above exceeded a value of 0.05 . If a model produced a "strange" selectivity pattern, the standard deviations of the prior distributions for the selectivity parameters and the standard deviations of any selectivity dev vectors were decreased proportionally relative to the values estimated for Model 15.7 in last year's assessment until the threshold value of 0.05 was satisfied.
4. The phrase "fairly non-informative prior" was interpreted as meaning a non-constraining uniform prior distribution.

As in previous assessments, development of the final versions of all models included calculation of the Hessian matrix and a requirement that all models pass a "jitter" test of 50 runs. In the event that a jitter run produced a better value for the objective function than the base run, then:

1. The model was re-run starting from the final parameter file from the best jitter run.
2. The resulting new control file, with the parameter estimates from the best jitter run incorporated as starting values, became the new base run.
3. The entire process (starting with a new set of jitter runs) was repeated until no jitter run produced a better value for the objective function than the most recent base run.

One difference from previous assessments is that, for this preliminary assessment, an attempt was made to standardize the bounds within which individual parameters were "jittered." Specifically, once a model was ready to be subjected to the jitter test, the bounds for each parameter in the model were adjusted to match the $99.9 \%$ confidence interval (based on the normal approximation obtained by inverting the Hessian matrix). A jitter rate (equal to half the standard deviation of the logit-scale distribution from which "jittered" parameter values are drawn) was set at 1.0 for all models. Standardizing the jittering process in this manner may not explore parameter space as thoroughly as in previous assessments; however, it should make the jitter rate more interpretable, and show the extent to which the identified minimum (local or otherwise) is well behaved.

Except for selectivity parameters and dev vectors in all models, all parameters were estimated with uniform prior distributions.

All selectivity devs were assumed to be additive (SS automatically assumes log recruitment devs to be additive).

Parameters estimated outside the assessment model (e.g., weight-at-length parameters, maturity-at-age parameters, ageing error matrix,) were likewise described in last year's final assessment (Thompson and Palsson 2015), and were not re-estimated for this preliminary assessment. In particular, the natural mortality rate $M$ was fixed at a value of 0.34 in Models 16.1-16.5, matching the value used in the EBS Pacific cod assessment.

## Model 15.7 Structure: Main Features

Model 15.7 bears some similarities to the model that has been accepted for use in management of the EBS Pacific cod stock since 2011 (Thompson 2015). Some of the main differences between Model 15.7 and the 2011-2015 EBS model are as follow:

1. In the data file, length bins ( 1 cm each) were extended out to 150 cm instead of 120 cm , because of the higher proportion of large fish observed in the AI.
2. Each year consisted of a single season instead of five.
3. A single fishery was defined instead of nine season-and-gear-specific fisheries.
4. The survey was assumed to sample age 1 fish at true age 1.5 instead of 1.41667 .
5. The standard deviation of log-scale age 0 recruitment ( $\sigma_{R}$ ) was estimated internally instead of being estimated outside the model.
6. Log-scale survey catchability $(\ln (Q))$ was estimated internally instead of being estimated outside the model, using a normal prior distribution with $\mu=0.00$ and $\sigma=0.11$ (values of prior parameters were obtained by averaging the values of the prior parameters from other age-structured AI groundfish assessments).
7. Initial abundances were estimated for the first ten age groups instead of the first three.
8. Selectivity for both the fishery and survey was modeled using a random walk with respect to age (SS selectivity-at-age pattern \#17) instead of the usual double normal.
9. A normal prior distribution for each selectivity parameter was used, tuned so that the schedule of prior means (across age) was consistent with logistic selectivity, with a constant (across age) prior standard deviation.
10. Potentially, each selectivity parameter was allowed to be time-varying with annual additive devs (normally distributed random deviations added to the base value of their respective parameter).

## Model 15.7 Structure: Iterative Tuning

For Model 15.7, the parameters described in this section were tuned most recently in the 2014 preliminary assessment.

## Iterative Tuning of Prior Distributions for Selectivity Parameters

Before allowing time-variability in any selectivity parameters, a pair of transformed logistic curves was fit to the point estimates of the fishery and survey selectivity schedules (a transformed logistic curve was used because the selectivity parameters in pattern \#17 consist of the backward first differences of selectivity on the log scale, rather than selectivity itself; Thompson and Palsson 2013). The respective transformed logistic curve (fishery or survey) was then used to specify a new set of means for the selectivity prior distributions (one for each age). A constant (across age) prior standard deviation was then computed such that no age had a prior CV (on the selectivity scale, not the transformed scale) less than $50 \%$, and at least one age had a prior CV of exactly $50 \%$.

The model was then run with the new set of prior means and constant prior standard deviations (one for the fishery, one for the survey), then a new pair of transformed logistic curves was fit to the results, and the process was repeated until convergence was achieved.

## Iterative Tuning of Time-Varying Selectivity Parameters

Two main loops were involved in the iterative tuning of time-varying selectivity parameters. These loops were designed to produce the quantities needed in order to use the method of Thompson and Lauth (2012, Annex 2.1.1; also Thompson in prep.) for estimating the standard deviation of a dev vector:

1. Compute an "unconstrained" estimate of the standard deviation of the set of year-specific devs associated with each age. The purpose of this loop was to determine the vector of devs that would be obtained if they were completely unconstrained by their respective $\sigma$. This was not always a straightforward process, as estimating a large matrix of age $\times$ year devs is difficult if the devs are unconstrained. In general, though, the procedure was to begin with a small (constant across age) value of $\sigma$; calculate the standard deviation of the estimated devs; then increase the value of $\sigma$ gradually until the standard deviation of the estimated devs reached an asymptote.
2. Compute an "iterated" estimate of the standard deviation of the set of year-specific devs associated with each age. This loop began with each $\sigma$ set at the unconstrained value estimated in the first loop. The standard deviation of the estimated devs then became the age-specific $\sigma$ for the next run, and the process was repeated until convergence was achieved.

The iteration was conducted separately for the fishery and survey.
Selectivity dev vectors for most ages were "tuned out" during the second loop (i.e., the os converged on zero). Specifically, selectivity dev vectors for all ages were tuned out except ages 4 and 6 for the fishery and ages 2,3 , and 7 for the survey.

## Results

## Overview

The following table summarizes the status of the stock as estimated by Models 16.1-16.5 ("Value" is the point estimate, "CV" is the ratio of the standard deviation of the point estimate to the point estimate itself, "FSB 2016" is female spawning biomass in 2016 ( t ), and "Bratio 2016" is the ratio of FSB 2016 to $B_{100 \%}$; color shading for FSB 2016 and Bratio 2016 extends from red (low) to green (high) for each quantity):

|  | Model 16.1 |  | Model 16.2 |  | Model 16.3 |  | Model 16.4 |  | Model 16.5 |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
|  | Quantity | Value | CV | Value | CV | Value | CV | Value | CV | Value |
| CV |  |  |  |  |  |  |  |  |  |  |
| FSB 2016 | 84,234 | 0.12 | 451,880 | 0.45 | 85,869 | 0.19 | 198,934 | 0.23 | 172,307 | 0.25 |
| Bratio 2016 | 0.46 | 0.09 | 0.62 | 0.15 | 0.29 | 0.13 | 0.47 | 0.10 | 0.47 | 0.13 |

These five models span wide ranges for these quantities. Estimates of FSB 2016 range from 84,000 t (Model 16.1) to 452,000 t (Model 16.2), and estimates of Bratio 2016 range from 0.29 (Model 16.3) to 0.62 (Model Model 16.2). The quantities FSB 2016 and Bratio 2016 tend to covary directly in these models (Model 16.1 is an exception). Although not directly comparable to female spawning biomass, Model 13.4 estimates a current trawl survey biomass of $69,000 \mathrm{t}$, with a CV of 0.16 .

## Goodness of fit

Objective function values and parameter counts are shown for each model in Table 2.1.3a, and multipliers used to adjust multinomial sample sizes are shown in Table 2.1.3b. Objective function values are not directly comparable across models, because different data files are used for some models, different constraints are imposed, and the number and types of parameters vary considerably.

Figure 2.1.1a shows the fits of all six models to the trawl survey abundance data; Figure 2.1.1b shows the fits of Models 16.2, and 16.4 to the IPHC longline survey abundance data; and Figure 2.1.1c shows the fits of Models 16.3 and 16.4 to the NMFS longline survey abundance data.

Table 2.1.4 shows goodness of fit for the survey abundance data (Models 16.1-16.5). Four measures are shown: root mean squared error (for comparison, the average log-scale standard error "бave" is also shown), mean normalized residual, standard deviation of normalized residuals, and correlation (observed:estimated). For the trawl survey data, Model 16.2 gives a root mean squared error close to oave, while all of the others give higher RMSEs. Models 16.2-16.5 all give mean normalized residuals in the $+/-0.1$ range. Models 16.1-16.5 all give standard deviation of normalized residuals greater than unity. Models 16.2-16.4 give correlations greater close to 0.90 or better. The two models that use the IPHC longline survey data both give mean normalized residuals close to zero, standard deviation of normalized residuals close to unity (note that these models inflate the input $\sigma$ values by an internally estimated amount, and the resulting estimates of oave are fairly high, in the 0.42-0.42 range), and correlations in the $0.46-0.54$ range. The two models that use the NMFS longline survey data perform similarly to those that use the IPHC data.

Sample size ratios for the size composition data (Models 16.1-16.5) are shown in Table 2.1 .5 (note that input sample sizes are the same for all models except for the trawl survey data in Model 16.5). These results can be summarized as follows:

- Measured as the ratio of the arithmetic mean effective sample size to the arithmetic mean input, the models give values well in excess of unity for all components except the NMFS longline survey, where the ratios obtained by Models 16.3 and 16.4 are both in the 0.63-0.64 range.
- Measured as the ratio of the harmonic mean effective sample size to the arithmetic mean input sample size, all models give noticeably smaller values, but still in excess of unity for all cases except, again, the NMFS longline survey.

Sample size ratios for the survey age composition data are shown in Table 2.1.6 (Models 16.1-16.5). Measured either as the ratio of the arithmetic means or the ratio of the harmonic mean effective sample size to the arithmetic mean input sample size, all of the models give values of 0.50 or less.

Figure 2.1.2 shows the fits to the survey size composition data, and Figure 2.1 . 3 shows the fits to the survey age composition data (Models 16.1-16.5 in both cases).

## Parameter estimates, time series, and retrospective analysis

Table 2.1.7 lists key parameters estimated internally in at least one of the models, along with their standard deviations. Note that the natural mortality rate $M$ was not estimated in any of the models, but was instead fixed at a value of 0.34 , based on the assessment of Pacific cod in the eastern Bering Sea (Thompson 2015). The estimates of log catchability for the trawl survey shown in Table 2.1.7 map into the following estimates of catchability on the natural scale, spanning the range 0.161 (Model 16.2) to 0.527 (Model 16.1):

| Model 16.1 |  | Model 16.2 |  | Model 16.3 |  | Model 16.4 |  | Model 16.5 |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Est. | SD | Est. | SD | Est. | SD | Est. | SD | Est. | SD |
| 0.527 | 0.079 | 0.161 | 0.409 | 0.452 | 0.119 | 0.300 | 0.180 | 0.355 | 0.197 |

Selectivity schedules are plotted for the fishery in Figure 2.1.4, the trawl survey in Figure 2.1.5a, the IPHC longline survey in Figure 2.1.5b, and the NMFS longline survey in Figure 2.1.5c.

Time series estimated by the models are shown for total biomass, female spawning biomass relative to $B_{100 \%}$, age 0 recruitment, and fishing mortality relative to $F_{40 \%}$ in Figures 2.1.6, 2.1.7, 2.1.8, and 2.1.9, respectively.

Figure 2.1.10 shows 10-year retrospectives of spawning biomass for each of the models, including Model 13.4 (where survey biomass is used in place of spawning biomass). Mohn's $\rho$ (revised) values for the models are shown below:

| Model 13.4 | Model 16.1 | Model 16.2 | Model 16.3 | Model 16.4 | Model 16.5 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| -0.034 | 0.015 | -0.296 | -0.245 | -0.397 | -0.106 |

## Acknowledgments

Anne Hollowed and the BSAI Groundfish Plan Team provided reviews of this preliminary assessment. IPHC staff collected the IPHC longline survey data, and Cindy Tribuzio computed the relative population numbers. Dana Hanselman provided the NMFS longline survey data.
